## **RESUMEN**

El objetivo de esta investigación es evaluar la configuración del programa ETABS para el análisis de una estructura de concreto armado de tres niveles en su dimensionamiento óptimo de acero para las combinaciones y estados de carga de la Norma E030. La investigación realizada es del tipo explicativa (causa-efecto), esta se determinó simulando las diferentes formas de configurar el programa ETABS para el análisis de la estructura de concreto armado aplicando las normas vigentes y así verificar el comportamiento de ETABS en el dimensionamiento óptimo de acero.

Se logró determinar el dimensionamiento de acero para tres simulaciones:

1.-Norma E030 espectro ( $0.75\text{SRSS}+0.25\text{ABS}$ ) 2.-Norma E030 espectro (CQC),  
3.- ACI 318-99 espectro (CQC), de estas simulaciones se obtuvo diferencias en el dimensionamiento de acero de hasta 10% en vigas y hasta 39% columnas. En conclusión luego del análisis de las simulaciones, el método recomendable para el diseño de una estructura es utilizando la Norma E030 espectro (CQC) ya que dimensiona menor acero en vigas 6% y en columnas 12% con respecto a la Norma E030 espectro ( $0.75\text{SRSS}+0.25\text{ABS}$ ).

**Palabras clave:** Evaluar configuración ETABS, Dimensionamiento de acero,

## **ABSTRACT**

The Objective of this research is evaluating the configuration of the program ETABS for the analysis of a concrete structure reinforced for three levels in its optimum measurement of steel for the combinations and states of load of the Rule E030. The realized research is an explanatory kind (Cause – Effect). It was determined simulating the different ways to configure the program ETABS for the analysis of a concrete reinforced structure applying the current rules thus verify the ETABS behavior in its optimum measurement of steel.

It was possible to determinate the measurement of steel for three simulations:

1.- Rule E030 spectrum ( $0.75\text{SRSS}+0.25\text{ABS}$ ), 2.- Rule E030 spectrum (CQC),  
3.-ACI 318-99 spectrum (CQC), Of these simulations we get differences in the dimensions of steel to 10% in girders and to 39% in columns. In conclusion after a harder analysis of the simulations, the advisable method for the design of a structure is using the Rule E030 spectrum (CQC) because it measures less steel in girders than in columns. In girders only 6% but in columns 12% according to the rule E030 spectrum ( $0.75\text{SRSS}+0.25\text{ABS}$ ).

**Key words:** Evaluate the configuration of ETABS, Measurement of steel.

## **FUNDAMENTOS DE LA TESIS**

### **INTRODUCCIÓN**

En la actualidad hay diversidad de programas computacionales para el diseño de una estructura de concreto armado, ETABS es un programa que usan ingenieros para realizar el diseño de estructuras de concreto armado pero la diversidad de parámetros y normas que intervienen en el diseño hace que se obtenga diferentes resultados para un mismo modelo. Esta incertidumbre en el comportamiento del programa para el diseño del acero en estructuras de concreto armado nos da pie a buscar un algoritmo en la configuración de los parámetros del programa ETABS. La diversidad de configuraciones y normas para el diseño de una estructura nos lleva a preguntarnos qué configuración permite que el programa ETABS logre el dimensionamiento de acero óptimo en estructuras de concreto armado.

En la actualidad el diseño mediante ETABS se lo ejecuta de modo vertical y sin un análisis consciente de lo que realmente se está ingresando al programa, por esta razón se realiza el estudio y análisis del programa ETABS para poder determinar la mejor configuración y así obtener el dimensionamiento óptimo de acero en el diseño de estructuras de concreto armado.

Con la presente tesis se dará una idea clara del comportamiento del programa ETABS en el diseño de acero en estructuras de concreto armado en el Perú y de esta manera tener un algoritmo claro para el ingreso de parámetros requeridos por ETABS, en el diseño de estructuras de concreto armado.

## **1. PROBLEMA DE LA INVESTIGACIÓN.**

### **1.1. Planteamiento del Problema.**

Con la llegada de computadoras digitales, los problemas de variable discreta pueden resolverse generalmente sin dificultad, aún cuando el número de elementos sea muy elevado. Como la capacidad de las computadoras es finita, los problemas continuos solo se pueden resolver de forma exacta mediante manipulaciones matemáticas.

Para vencer la dificultad que presenta la solución de problemas continuos reales, ingenieros y matemáticos han ido proponiendo a través de los años diversos métodos de discretización. Los ingenieros, suelen enfrentar el problema intuitivamente creando una analogía entre elementos discretos reales y porciones finitas de un dominio continuo; de ésta analogía directa adoptada por los ingenieros, nace el método de “elementos finitos” como procedimiento general de discretización de los problemas continuos planteados por expresiones definidas matemáticamente<sup>1</sup>.

Durante los últimos años la enseñanza del análisis estructural ha cambiado en todo el mundo, en nuestro país pocas universidades dictan el curso de elementos finitos, al menos como una introducción, para entender las limitaciones y aproximaciones de los Software especializados en el análisis estructural como ETABS, SAP2000, etc.

El programa ETABS es uno de los programas que tiene en cuenta una cantidad apreciable de propiedades necesarias para el análisis de un modelo matemático, el cual permite realizar un diseño de la estructura de forma rápida. Por lo que en la presente investigación se evaluará el comportamiento del programa ETABS en

---

<sup>1</sup> El método de los elementos finitos. O. C. Zienkiewicz. Pg. 2

el diseño de estructuras de concreto armado, así como determinar la mejor configuración de cargas y parámetros para un óptimo dimensionamiento del acero de diseño.

El problema principal se fundamenta en que el programa ETABS cuenta con diversas formas de configuración para el cálculo de una estructura de concreto armado, estas pueden ser una configuración predeterminada del programa o puede ser configurado por el usuario las cuales nos arrojan diferentes resultados en el dimensionamiento del acero. Esta incertidumbre en el comportamiento del programa para el dimensionamiento del acero en estructuras de concreto armado nos da pie a buscar una sistematización en la configuración de parámetros del programa ETABS para obtener un óptimo dimensionamiento de acero.

### 1.2. Formulación del Problema.

¿Qué configuración permite que el programa ETABS logre el dimensionamiento de acero óptimo en el diseño de estructuras de concreto armado?

### 1.3. Justificación de la investigación.

En la actualidad el diseño mediante programas computarizados son más frecuentes entre los ingenieros del Perú y el mundo pero muchas veces el proceso indicado en los tutoriales se lo ejecuta de modo vertical y sin un análisis consciente de lo que realmente se está ingresando al programa, por esta razón se realiza este estudio para evaluar el programa ETABS y poder determinar la mejor configuración que permita obtener el dimensionamiento óptimo de acero en el diseño de estructuras de concreto armado.

#### **1.4. Alcances y Limitaciones.**

El diseño con el programa ETABS nos brinda diversos materiales con los cuales puede diseñar una estructura, el presente estudio se limita al diseño de estructuras de concreto armado relacionando al dimensionamiento acero en vigas y columnas de una estructura teniendo en consideración los tipos de carga, estados de carga y masa en una estructura para su diseño.

El programa ETABS nos brinda variadas formas de diseño, esto constituye una ventaja, sin embargo; el tutorial original, por estar en otro idioma, es un problema para el pueblo latino. Las traducciones son personalizadas y muchas veces se cambia la esencia del pensamiento del diseñador del programa.

## **2. OBJETIVOS.**

### **2.1. Objetivo general.**

- Evaluar la configuración del programa ETABS, para el óptimo dimensionamiento del acero en una estructura de concreto armado.

### **2.2. Objetivos específicos.**

- Determinar la mejor configuración del programa ETABS para el dimensionamiento de acero en una estructura de concreto armado.
- Establecer un algoritmo para diseñar estructuras de concreto, con el programa ETABS.

### **3. HIPOTESIS.**

#### **3.1.Hipótesis.**

La correcta configuración del programa ETABS para el diseño de estructuras de concreto armado optimiza el dimensionamiento de acero.

### **4. VARIABLES.**

#### **Variable independiente:**

- Correcta configuración del programa ETABS para diseño de concreto armado.

#### **Variable dependiente:**

- Optimización en el Dimensionamiento de acero.

### **5. LOCALIZACIÓN.**

Las construcciones de concreto armado son muy comunes en el Perú en consecuencia el presente estudio abarca a todo el territorio peruano y especialmente se centra en la ciudad de Cajamarca con un aporte en el diseño de estructuras de concreto armado aplicando el programa ETABS.

### **6. TIPO DE INVESTIGACIÓN Y ANÁLISIS.**

#### **6.1. Tipo de investigación.**

Será de tipo EXPLICATIVA, porque se pretende determinar la causa que genere la optimización del dimensionamiento de acero de modo que se encuentre la sistematización que permita comprender la correcta configuración del programa ETABS. Esto permitirá proponer una metodología para ejecutar el programa ETABS, y lograr un óptimo dimensionamiento de acero.

### **6.2. Unidad de estudio.**

Se considera como unidad de estudio la estructura de concreto armado de un edificio de 3 niveles, la cual se evaluará con el programa ETABS.

### **6.3. Instrumento de recolección y procesamiento de datos.**

Para la sistematización de la información se utilizará el programa ETABS, con los diferentes tipos de configuración que este nos permite y así obtener el dimensionamiento óptimo de acero de la estructura en estudio.

### **6.4. Descripción del diseño.**

Será del tipo explicativa, CAUSA-EFECTO. Se realizará manipulando las variables independientes en el programa ETABS, para observar el comportamiento del programa ETABS en el dimensionamiento de acero.

Para el diseño en el programa ETABS se tiene que tener definida: la arquitectura, las normas a emplear y los materiales a usar, adicionalmente se tiene que tener un estudio de suelos para determinar las propiedades de suelo en la que se fundara la estructura y así obtener el cuadro de pseudo-aceleraciones real.

Luego de realizar los estudios previos se procede con el:

1. Pre-dimensionamiento de la estructura a diseñar para esto existen métodos y procedimientos ya definidos los cuales siguen ciertas recomendaciones.
2. Generar un nuevo proyecto en el programa ETABS, inicialmente se tiene generar un GRID y definir los materiales con los que se va a trabajar el modelo es

nuestro caso será el concreto de 210kg/cm<sup>2</sup>, luego de definir los materiales se procede a asignar las secciones de vigas, columnas, losas etc.

3. Luego de idealizar nuestra estructura con los elementos que la conforman se procede a definir las cargas CV y CM.

Realizamos el análisis sísmico por el método dinámico, la cual se realiza mediante los siguientes pasos:

4. Definimos la masa del modelo en el programa.
5. Definir el espectro de aceleraciones.
6. Escogemos la combinación de cargas para resolver el diseño.
7. Analizamos el modelo por combinaciones manuales o predeterminada.
8. Obtenemos los resultados del dimensionamiento del acero de las diferentes configuraciones.

#### 6.5. Análisis de datos.

Se evaluara el dimensionamiento del acero en estructuras de concreto armado.

Estos datos del dimensionamiento de acero de las diferentes combinaciones del programa ETABS serán discutidas para aceptar la validez de éstas mediante tres simulaciones:

- a. Norma E030 espectro (0.75SRSS+0.25ABS)
- b. Norma E030 espectro (CQC)
- c. ACI 318-99 espectro (CQC)

Luego se evaluará el dimensionamiento de acero y se determinará el óptimo; logrando de esta manera la simulación más adecuada del programa ETABS.

## CAPÍTULO I. MARCO TEÓRICO

### 1.1. Antecedentes.

#### 1.1.1. Internacionales.

Edward L. Wilson (1970), lanzó en EE.UU el primer programa completo de análisis estructural, llamado SAP, el cual representaba para su época el estado del arte de los procedimientos numéricos para la ingeniería estructural. En esa época, el programa era utilizado en computadoras de gran tamaño, por lo que estuvo restringido a las organizaciones gubernamentales y a las grandes compañías.

A finales de los años 70, aparecieron las computadoras personales, lo cual hizo que los programas de análisis también se volvieran populares en las pequeñas compañías y entre algunos usuarios individuales.

En el año 1980, se desarrolló la primera aplicación para análisis estructural en 3D para computadoras personales.

Actualmente, los programas de análisis y diseño de estructuras permiten realizar rápidamente la creación del modelo a través del dibujo de un conjunto de objetos que poseen propiedades<sup>1</sup>

#### 1.1.2. Nacionales.

No se registra antecedentes solo se aprecia una tendencia a comprender el programa ETABS a través de su aplicación.

---

<sup>1</sup> Revisar la información de la página web perteneciente a la empresa CSI Computers & Structures inc. (<http://www.csiberkeley.com/USGS/backgrounder.pdf>).

Para el desarrollo del presente proyecto, se consultaron diferentes trabajos e investigaciones que guardan relación con el trabajo que se pretende hacer. A continuación se indican las investigaciones consultadas.

- En la tesis diseño de un edificio de concreto armado de 7 niveles, se desarrolló el análisis y diseño estructural de un edificio multifamiliar de siete pisos y un semisótano, ubicado en el distrito de Surquillo, provincia de Lima, sobre un área de terreno de 390 m<sup>2</sup> aproximadamente. El suelo de cimentación corresponde a una grava con una capacidad portante de 30.00 ton/m<sup>2</sup>. El diseño se realizó siguiendo lo establecido en el Reglamento Nacional de Edificaciones. El sistema estructural del edificio está compuesto por muros de corte, columnas y vigas de concreto armado<sup>2</sup>.
- La tesis Análisis y diseño de edificios asistido por computadoras se ha desarrollado con la finalidad de servir de material didáctico a todas aquellas personas que pretendan iniciarse en el uso de un programa de análisis de edificios, en este caso el programa ETABS<sup>3</sup>.
- En la tesis el diseño estructural de un edificio de viviendas de seis niveles, se ha desarrollado el análisis y diseño estructural de un edificio de 6 pisos de concreto armado, destinado a vivienda. Este edificio se encuentra ubicado en el distrito de Santiago de Surco en la ciudad de Lima sobre un terreno de capacidad portante de 4.0 kg/cm<sup>2</sup> a 1.20m. de profundidad<sup>4</sup>.

### **1.1.3. Locales.**

No sé registra antecedentes solo se aprecia una tendencia a comprender el programa ETABS y aplicarla al diseño de estructuras.

## **1.2. Bases Teóricas.**

### **1.2.1. Elementos finitos.**

El método de los elementos finitós, es un procedimiento basado en técnicas computacionales, que puede ser usado para analizar estructuras y diferentes sistemas continuos. Es un método numérico versátil, y que es ampliamente aplicado para resolver problemas que cubren casi todo el espectro de análisis ingenieriles. Sus aplicaciones comunes, incluyen el comportamiento de sistemas estáticos, dinámicos y térmicos. Los avances en el hardware, han facilitado y aumentado la eficiencia del software de elementos finitos, para la solución de sistemas complejos de ingeniería sobre computadores personales<sup>5</sup>.

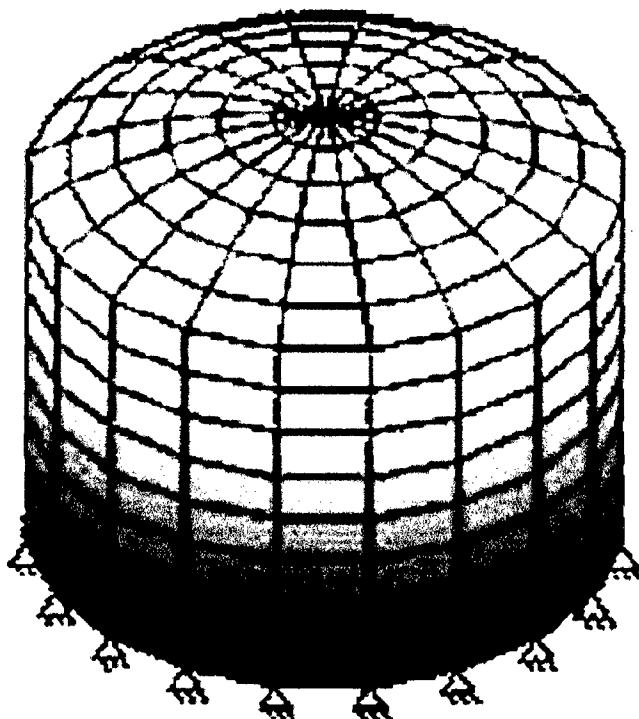

### **1.2.2. Descripción General del método de los Elementos Finitos y pasos para el análisis de Elementos Finitos**

Calcular las deformaciones, tensiones y esfuerzos, con métodos clásicos de análisis, se logra a través de la solución manual de sus ecuaciones, y sus condiciones de frontera. El uso de métodos clásicos, es probablemente la mejor forma de analizar estructuras simples; no obstante, su uso es poco aconsejable cuando el sistema es complejo. En estos casos la mejor alternativa, es usualmente una solución obtenida con el método de los elementos finitos. La primera diferencia entre los métodos clásicos y los elementos finitos son la forma de ver la estructura y el consiguiente procedimiento de solución. Los métodos

---

<sup>5</sup> Celigueta, J. (2008) 3ra. MEF para análisis estructural, pag.1

clásicos consideran la estructura como continuo, cuyo comportamiento es gobernado por ecuaciones diferenciales parciales u ordinarias. El método de elementos finitos considera la estructura como el ensamblaje de un número finito de partículas pequeñas. El comportamiento de las partículas, y de toda la estructura, es obtenida por la formulación de un sistema algebraico de ecuaciones que puede ser solucionado por medio de un computador. Las partículas de tamaño finito, son llamadas elementos finitos. Los puntos donde los elementos finitos son interconectados, son conocidos como nodos, y el procedimiento de selección de nodos es llamado discretización o modelización<sup>6</sup>

**Figura 01** Tanque cilíndrico modelado con elementos finitos

---

<sup>6</sup> Celigueta, J. (2008) 3ra. MEF para análisis estructural, pag.1-2

### **1.2.3. Fundamentos de la modelización de elementos finitos**

#### **1.2.3.1. Consideraciones del modelado**

El objetivo del análisis por medio del método de los elementos finitos, es determinar de forma precisa la respuesta de un sistema modelado con una cantidad finita de elementos y sujeto a unas cargas determinadas. En la generación de un modelo por elementos finitos, siempre se tiene presente que se está desarrollando un modelo el cual es una idealización de un sistema físico real. Con muy pocas excepciones, como el del análisis estático de vigas simples, marcos y sistemas de membranas, el método de elementos finitos no genera una solución ‘exacta’. Sin embargo, con un modelo adecuado, se puede obtener una solución precisa. Cuando la formulación analítica de un problema es difícil de desarrollar, FEM (Finite Element Method) provee uno de los más fiables métodos para atacar el problema<sup>7</sup>.

#### **1.2.3.2. Tipos de Elementos Finitos**

Esta sección describe muchas características sobresalientes de los elementos más utilizados denominados: truss, beam, plane stress, plane strain, axisymmetric, membrane, plate, shell, solid ó brick, tetrahedral, hexahedral, boundary, y gap. Los programas comerciales de elementos finitos poseen una gran cantidad de elementos en sus librerías. Sin embargo, la mayoría de las estructuras y aplicaciones mecánicas pueden ser solucionadas con los elementos básicos ya mencionados.

Dependiendo la dimensión, los elementos básicos se pueden dividir en tres categorías: elemento de línea, área y volumen. Truss, beam y los elementos de

---

<sup>7</sup> Celigüeta, J. (2008) 3ra. MEF para análisis estructural, pag.3

restricción, son de línea. Plane stress, plain strain, axisymmetric, membrane, plate y shell son elementos de área. Solid ó brick, tetrahedral y hexahedral son elementos de volumen. Los criterios para la selección del elemento apropiado para cada aplicación se verán más adelante<sup>8</sup>.

### Elementos ‘Truss’

El elemento truss, es un elemento caracterizado básicamente porque solo puede comportarse como un miembro sometido a dos fuerzas (se sabe por tanto que estas cargas deben estar dirigidas a lo largo del eje longitudinal del elemento).

Los elementos Truss solo pueden ser sometidos a tracción o compresión. De esta forma, la única propiedad de la sección que se debe especificar es el área axial del elemento. La figura 2 muestra la geometría y las fuerzas nodales en un elemento truss tridimensional. Como se muestra en la figura, un elemento truss tridimensional posee tres grados de libertad por nodo, esto es tres desplazamientos sobre los ejes globales X, Y y Z<sup>9</sup>.

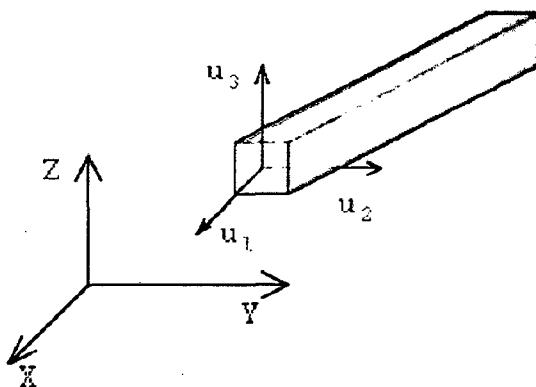

Figura 2 Elemento Truss tridimensional

<sup>8</sup> Celigueta, J. (2008) 3ra. MEF para análisis estructural, pag.4

<sup>9</sup> Celigueta, J. (2008) 3ra. MEF para análisis estructural, pag.5

## Elementos 'Beam'

El elemento Beam, es probablemente el más usado. Además de sus aplicaciones obvias en estructuras, muchos otros sistemas, como uniones mecánicas, sistemas de conductos, tuberías y vigas en puentes pueden ser modeladas con el elemento 'beam'.

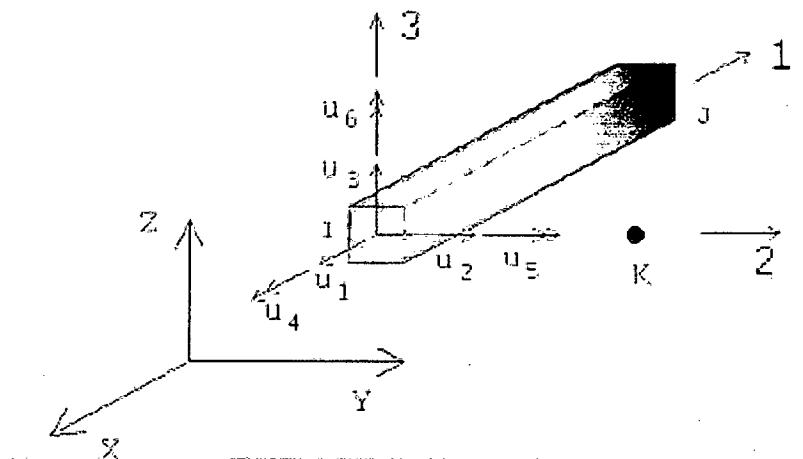

Figura 3 Elemento Beam

## Elementos Elásticos bidimensionales

Hay tres tipos de elementos bidimensionales:

1. Plane Stress Elements (Esfuerzo plano)
2. Plane Strain Elements (Deformación plana)

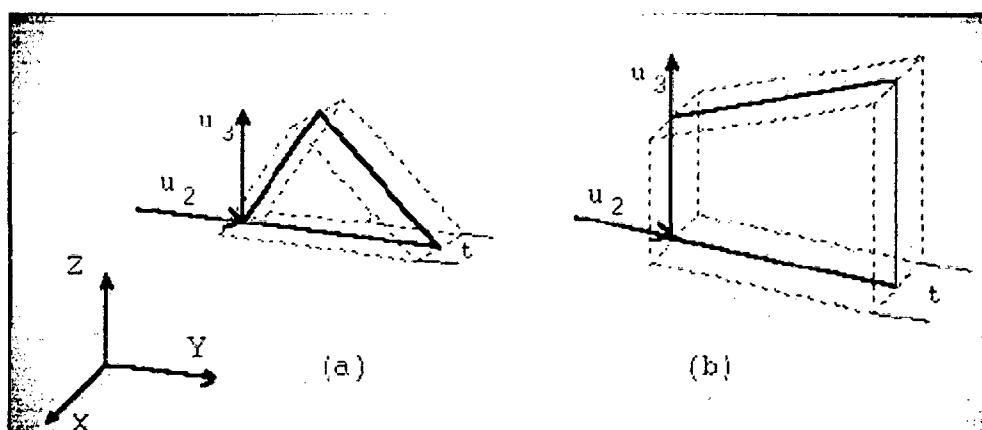

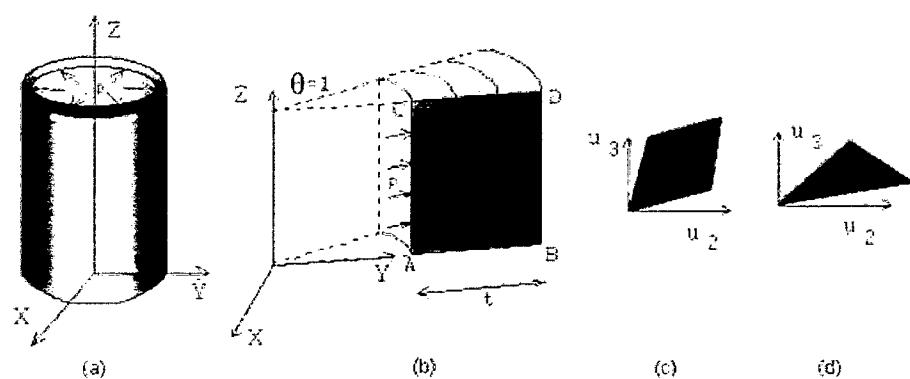

Figura 4 Elemento bidimensional en esfuerzo plano: (a) Triangular; (b) Cuadrilátero

### 3. Axisymmetric Elements (Elementos Axisimétricos ).

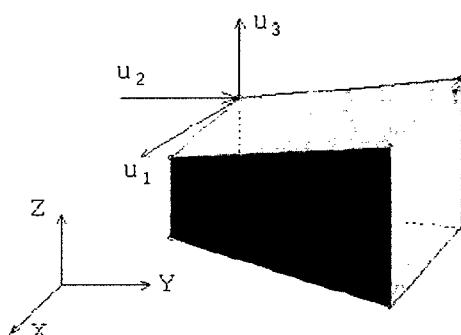

Tanques de acero y concreto, rotores, conchas, toberas y contenedores son algunos ejemplos representativos de estructuras axisimétricas. De forma similar a las estructuras tridimensionales que están bajo condición de esfuerzo plano o deformación plana, las estructuras axisimétricas sometidas a cargas axisimétricas, pueden ser analizadas en un modelo bidimensional<sup>10</sup>.

**Figura 5** (a) Cilindro bajo presión interna; (b) Modelo Axisimétrico; (c) Elemento Cuadrilátero; (d) Elemento Triangular.

### Sólidos elásticos tridimensionales ó elementos ‘Brick’

Los elementos sólidos son elementos tridimensionales con tres grados de libertad translacional por nodo<sup>11</sup>.

**Figura 6** Elemento brick y sus grados de libertad por nodo (8 nodos)

<sup>10</sup> Celigueta, J. (2008) 3ra. MEF para análisis estructural, pag.7

<sup>11</sup> Celigueta, J. (2008) 3ra. MEF para análisis estructural, pag.7-8

## Elementos ‘Tetrahedral’ and ‘Hexahedral’

Así como los elementos brick, los elementos ‘tetrahedral’ y ‘hexahedral’ pueden ser usados para modelar estructuras tridimensionales. El tetraedro puede ser visto como un triangulo en tercera dimensión, como se ve en la figura 7, mientras que el hexaedro puede ser visto como un cuadrilátero extendido en la tercera dimensión. Se puede apreciar entonces que el hexaedro tiene la misma geometría del elemento brick de 8 nodos. La diferente entre estos dos, es la formulación y precisión computacional. Por lo general los elementos tetraedro y el hexaedro poseen solo tres grados de libertad por nodo, y la precisión de estos elementos se puede incrementar colocando nodos en la mitad de los lados<sup>12</sup>.

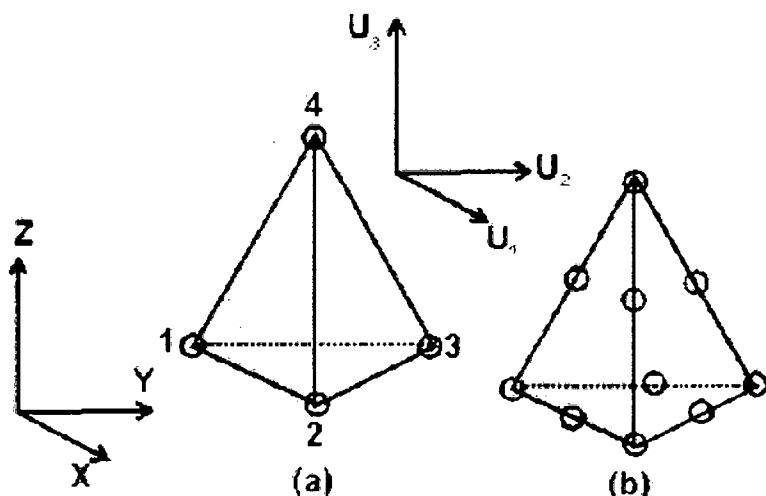

Figura 7 (a) Tetraedro de 4nodos; (b) tetraedro de 10 nodos.

### 1.2.3. Selección del tipo de Elementos

Antes de seleccionar el tipo de elemento para el modelo de una estructura, se debe primero dibujar un bosquejo del sistema físico indicando su geometría, condiciones de frontera, cargas y discontinuidades geométricas o de material. El

<sup>12</sup> Celigueta, J. (2008) 3ra. MEF para análisis estructural, pag.8

bosquejo debe además incluir un sistema de coordenadas globales y las dimensiones de la estructura.

Después, se debe examinar si el modelo puede ser reducido, o simplificado. Esfuerzo plano, deformación plana y modelos axisimétricos, permiten la reducción de problemas tridimensionales a bidimensionales. Además la presencia de planos de simetría permite modelar sólo una parte de la estructura. El uso apropiado de la simetría en modelos estáticos ya fue discutido.

El bosquejo de un sistema físico, puede ayudar en la selección del elemento apropiado. Por ejemplo, para modelar cargas transversales o axiales en elementos mecánicos, eléctricos y estructuras civiles, se pueden usar elementos beam o truss. Elementos de esfuerzos planos son apropiados para modelar en el plano de acción, placas y vigas cortas. Elementos de deformación plana son usualmente utilizados para modelar paredes de contención y largos diques. Los elementos axisimétricos son usados para modelar estructuras que son rotacionalmente simétricas sobre uno de los ejes y cargado simétrica o antisimétricamente sobre el mismo eje, como los cilindros sometidos a presión interna<sup>13</sup>.

#### **1.2.3.4. El Método de los Elementos Finitos recurre a la hipótesis de discretización, que se basa en lo siguiente.**

- El continuo se divide por medio de líneas o superficies imaginarias en una serie de regiones contiguas y disjuntas entre sí, de formas geométricas sencillas y normalizadas, llamadas *elementos finitos*.

---

<sup>13</sup> Celigüeta, J. (2008) 3ra. MEF para análisis estructural, pag.9

- Los elementos finitos se unen entre sí en un número finito de puntos, llamados *nudos*.
- Los desplazamientos de los nudos son las incógnitas básicas del problema, y éstos determinan únicamente la configuración deformada de la estructura. Sólo estos desplazamientos nodales se consideran independientes.
- El desplazamiento de un punto cualquiera, viene únicamente determinado por los desplazamientos de los nudos del elemento al que pertenece el punto. Para ello se definen para cada elemento, unas *funciones de interpolación* que permiten calcular el valor de cualquier desplazamiento interior por interpolación de los desplazamientos nodales. Estas funciones de interpolación serán de tal naturaleza que se garantice la compatibilidad de deformaciones necesaria en los contornos de unión entre los elementos.
- Las funciones de interpolación y los desplazamientos nodales definen únicamente el estado de deformaciones unitarias en el interior del elemento. Éstas, mediante las ecuaciones constitutivas del material definen el estado de tensiones en el elemento y por supuesto en sus bordes.
- Para cada elemento, existe un sistema de fuerzas concentradas en los nudos, que equilibran a las tensiones existentes en el contorno del elemento, y a las fuerzas exteriores sobre él actuantes<sup>14</sup>.

---

<sup>14</sup> Celigüeta, J. (2008) 3ra. MEF para análisis estructural, pag.15

#### **1.2.4. DEFINICIONES.**

**Agregado:** Material granular, de origen natural o artificial, como arena, grava, piedra triturada y escoria de hierro de alto horno, empleado con un medio cementante para formar concreto o mortero hidráulico.

**Agregado denominado Hormigón:** Material compuesto de grava y arena empleado en su forma natural de extracción.

**Agregado Fino:** Agregado proveniente de la desintegración natural o artificial, que pasa el tamiz 9,5 mm (3/8").

**Agregado Grueso:** Agregado retenido en el tamiz 4,75 mm (Nº 4), proveniente de la desintegración natural o mecánica de las rocas. N.T.E. E.60 CONCRETO ARMADO 14

**Carga de servicio:** La carga (sin amplificar) especificada en la Norma NTE. E.020 Cargas, del Reglamento Nacional de Edificaciones del cual esta Norma forma parte.

**Carga amplificada o factorizada:** La carga, multiplicada por los factores de carga apropiados, que se utiliza para diseñar los elementos utilizando el método de diseño por resistencia de esta Norma<sup>15</sup>.

**Cemento:** Material pulverizado que por adición de una cantidad conveniente de agua forma una pasta aglomerante capaz de endurecer, tanto bajo el agua como en el aire. Quedan excluidas las cales hidráulicas, las cales aéreas y los yesos.

**Columna:** Elemento con una relación entre altura y menor dimensión lateral mayor que tres, usado principalmente para resistir carga axial de compresión.

**Concreto:** Mezcla de cemento Portland o cualquier otro cemento hidráulico, agregado fino, agregado grueso y agua, con o sin aditivos.

---

<sup>15</sup> Reglamento Nacional de Edificaciones Norma E060, pag.13-17

**Concreto estructural:** Todo concreto utilizado con propósitos estructurales incluyendo al concreto simple y al concreto reforzado.

**Estribo:** Refuerzo colocado perpendicularmente o en ángulo con respecto al refuerzo longitudinal, empleado para resistir esfuerzos de cortante y de torsión en un elemento estructural. Los estribos también cumplen función de control del pandeo de las barras longitudinales y de confinamiento al concreto.

**Losa:** Elemento estructural de espesor reducido respecto de sus otras dimensiones usado como techo o piso, generalmente horizontal y armado en una o dos direcciones según el tipo de apoyo existente en su contorno. Usado también como diafragma rígido para mantener la unidad de la estructura frente a cargas horizontales de sismo<sup>16</sup>.

**Módulo de elasticidad:** Relación entre el esfuerzo normal y la deformación unitaria correspondiente, para esfuerzos de tracción o compresión menores que el límite de proporcionalidad del material.

**Muro estructural:** Elemento estructural, generalmente vertical empleado para encerrar o separar ambientes, resistir cargas axiales de gravedad y resistir cargas perpendiculares a su plano proveniente de empujes laterales de suelos o líquidos.

**Muro de corte o Placa:** Muro estructural diseñado para resistir combinaciones de fuerzas cortantes, momentos y fuerzas axiales inducidas por cargas laterales.

**Pórtico resistente a momentos:** Pórtico en el cual los elementos y los nudos resisten las cargas a través de flexión, cortante y fuerza axial.

**Refuerzo corrugado:** Barras de refuerzo corrugado, mallas de barras, alambre corrugado o refuerzo electrosoldado de alambre, que cumplan con 3.5.3 E060<sup>17</sup>.

---

<sup>16</sup> Reglamento Nacional de Edificaciones Norma E060, pag.13-17

<sup>17</sup> Reglamento Nacional de Edificaciones Norma E060, pag.13-17

**Resistencia a la fluencia:** Resistencia a la fluencia mínima especificada o punto de fluencia del refuerzo. La resistencia a la fluencia o el punto de fluencia deben determinarse en tracción, de acuerdo con las Normas Técnicas Peruanas (NTP) aplicables, con las modificaciones de 3.5 de esta Norma.

**Resistencia de diseño:** Resistencia nominal multiplicada por el factor de reducción de resistencia  $\Phi$  que corresponda.

**Resistencia especificada a la compresión del concreto ( $f'_c$ ):** Resistencia a la compresión del concreto empleada en el diseño y evaluada de acuerdo con las consideraciones del Capítulo 5 (NTP E060), expresada en MPa. Cuando dicha cantidad esté bajo un signo radical, se quiere indicar sólo la raíz cuadrada del valor numérico, por lo que el resultado está en MPa.

**Resistencia Nominal:** Resistencia de un elemento o una sección transversal calculada con las disposiciones e hipótesis del método de diseño por resistencia de esta Norma, antes de aplicar el factor de reducción de resistencia.

**Resistencia Requerida:** Resistencia que un elemento o una sección transversal debe tener para resistir las cargas amplificadas o los momentos y fuerzas internas correspondientes combinadas según lo estipulado en esta Norma.

**Viga:** Elemento estructural que trabaja fundamentalmente a flexión y cortante<sup>18</sup>.

### **1.2.5. Diseño sismo-resistente.**

#### **1.2.5.1 Filosofía y Principios del diseño sismo-resistente**

La filosofía del diseño sismorresistente consiste en:

- a. Evitar pérdidas de vidas
- b. Asegurar la continuidad de los servicios básicos

---

<sup>18</sup> Reglamento Nacional de Edificaciones Norma E060, pag.13-17

- c. Minimizar los daños a la propiedad.

Se reconoce que dar protección completa frente a todos los sismos no es técnica ni económicamente factible para la mayoría de las estructuras. En concordancia con tal filosofía se establecen en esta Norma los siguientes principios para el diseño:

- a. La estructura no debería colapsar, ni causar daños graves a las personas debido a movimientos sísmicos severos que puedan ocurrir en el sitio.
- b. La estructura debería soportar movimientos sísmicos moderados, que puedan ocurrir en el sitio durante su vida de servicio, experimentando posibles daños dentro de límites aceptables<sup>19</sup>.

#### **1.2.5.2 Presentación del Proyecto.**

Los planos del proyecto estructural deberán contener como mínimo la siguiente información:

- a. Sistema estructural sismorresistente.
- b. Parámetros para definir la fuerza sísmica o el espectro de diseño.
- c. Desplazamiento máximo del último nivel y el máximo desplazamiento relativo de entrepiso<sup>20</sup>.

#### **1.2.5.3 Parámetros de Sitio.**

##### **1.2.5.3.1. Zonificación (Z):**

El territorio nacional se considera dividido en tres zonas, como se muestra en la Figura N° 1. La zonificación propuesta se basa en la distribución espacial de la sismicidad observada, las características generales de los movimientos sísmicos y la atenuación de éstos con la distancia epicentral, así como en información neotectónica.

---

<sup>19</sup> Reglamento Nacional de Edificaciones Norma E030, pag.208

<sup>20</sup> Reglamento Nacional de Edificaciones Norma E030, pag.208

A cada zona se asigna un factor Z según se indica en la **Tabla N°1**. Este factor se interpreta como la aceleración máxima del terreno con una probabilidad de 10 % de ser excedida en 50 años.

**Tabla 01: Factor de Zona**

| ZONA | Z    |
|------|------|
| 3    | 0.4  |
| 2    | 0.3  |
| 1    | 0.15 |

#### **1.2.5.3.2. Microzonificación Sísmica y Estudios de Sitio.**

##### **a. Microzonificación Sísmica.**

Será requisito la realización de los estudios de micro-zonificación en los siguientes casos:

- Áreas de expansión de ciudades.
- Complejos industriales o similares.
- Reconstrucción de áreas urbanas destruidas por sismos y fenómenos asociados

Los resultados de estudios de microzonificación serán aprobados por la autoridad competente, que puede solicitar informaciones o justificaciones complementarias en caso lo considere necesario<sup>21</sup>.

##### **b. Estudios de Sitio.**

Son estudios similares a los de microzonificación, aunque no necesariamente en toda su extensión. Estos estudios están limitados al lugar del proyecto y suministran información sobre la posible modificación de las acciones sísmicas y otros fenómenos naturales por las condiciones locales. Su objetivo principal es determinar los parámetros de diseño. No se considerarán parámetros de diseño inferiores a los indicados en esta Norma.

#### **1.2.5.4. Condiciones Geotécnicas.**

---

<sup>21</sup> Reglamento Nacional de Edificaciones Norma E030, pag.209

Para los efectos de esta Norma, los perfiles de suelo se clasifican tomando en cuenta las propiedades mecánicas del suelo, el espesor del estrato, el período fundamental de vibración y la velocidad de propagación de las ondas de corte<sup>22</sup>.

Los tipos de perfiles de suelos son cuatro y se muestran en la **Tabla 02**:

**Tabla 02: Parámetros de Suelo**

| Tipo           | Descripción                                     | T <sub>p</sub> (s) | S   |
|----------------|---|--------------------|-----|
| S <sub>1</sub> | Roca o suelos muy rígidos                       | 0.4                | 1.0 |
| S <sub>2</sub> | Suelos intermedios                              | 0.6                | 1.2 |
| S <sub>3</sub> | Suelos flexibles o con estratos de gran espesor | 0.9                | 1.4 |
| S <sub>4</sub> | Condiciones excepcionales                       | *                  | *   |

(\*) Los valores de T<sub>p</sub> y S para este caso serán establecidos por el especialista, pero en ningún caso serán menores que los especificados para el perfil tipo S3.

#### 1.2.5.5. Factor de Amplificación Sísmica

De acuerdo a las características de sitio, se define el factor de amplificación sísmica (C) por la siguiente expresión:

$$C = 2.5 * \left( \frac{T_p}{T} \right) \leq 2.5, \text{ Donde } T = \frac{h_n}{C_T}$$

T es el período según se define en el Artículo 17 (17.2) ó en el Artículo 18 (18.2 a). Este coeficiente se interpreta como el factor de amplificación de la respuesta estructural respecto de la aceleración en el suelo<sup>23</sup>.

---

<sup>22</sup> Reglamento Nacional de Edificaciones Norma E030, pag.209

<sup>23</sup> Reglamento Nacional de Edificaciones Norma E030, pag.209

#### 1.2.5.6. Categoría de las Edificaciones

Cada estructura debe ser clasificada de acuerdo con las categorías indicadas en la Tabla N° 3. El coeficiente de uso e importancia (U), definido en la Tabla N° 3 se usará según la clasificación que se haga.

**Tabla 03: Categoría de las Edificaciones**

| Categoría                      | Descripción  | Factor U |
|--------------------------------|--|----------|
| A<br>Edificaciones Esenciales  | Edificaciones esenciales cuya función no debería interrumpirse inmediatamente después que ocurra un sismo, como hospitales, centrales de comunicaciones, cuarteles de bomberos y policía, subestaciones eléctricas, reservorios de agua. Centros educativos y edificaciones que puedan servir de refugio después de un desastre. También se incluyen edificaciones cuyo colapso puede representar un riesgo adicional, como grandes hornos, depósitos de materiales inflamables o tóxicos. | 1.5      |
| B<br>Edificaciones Importantes | Edificaciones donde se reúnen gran cantidad de personas como teatros, estadios, centros comerciales, establecimientos penitenciarios, o que guardan patrimonios valiosos como museos, bibliotecas y archivos especiales. También se considerarán depósitos de granos y otros almacenes importantes para el abastecimiento  | 1.3      |
| C<br>Edificaciones Comunes     | Edificaciones comunes, cuya falla ocasionaría pérdidas de cuantía intermedia como viviendas, oficinas, hoteles, restaurantes, depósitos e instalaciones industriales cuya falla no acarree peligros adicionales de incendios, fugas de contaminantes, etc.   | 1.0      |
| D<br>Edificaciones Menores     | Edificaciones cuyas fallas causan pérdidas de menor cuantía y normalmente la probabilidad de causar víctimas es baja, como cercos de menos de 1,50m de altura, depósitos temporales, pequeñas viviendas temporales y construcciones similares.   | (*)      |

(\*) En estas edificaciones, a criterio del proyectista, se podrá omitir el análisis por fuerzas sísmicas, pero deberá proveerse de la resistencia y rigidez adecuadas para acciones laterales<sup>24</sup>.

<sup>24</sup> Reglamento Nacional de Edificaciones Norma E030, pag.210

### **1.2.5.7. Sistemas Estructurales**

Los sistemas estructurales se clasificarán según los materiales usados y el sistema de estructuración sismorresistente predominante en cada dirección tal como se indica en la Tabla N°4. Según la clasificación que se haga de una edificación se usará un coeficiente de reducción de fuerza sísmica (R). Para el diseño por resistencia última las fuerzas sísmicas internas deben combinarse con factores de carga unitarios. En caso contrario podrá usarse como (R) los valores establecidos en Tabla N°4 previa multiplicación por el factor de carga de sismo correspondiente.

**Tabla 04: Sistemas Estructurales**

| Sistema Estructural   | Coeficiente de Reducción, R<br>Para estructuras regulares (*) (**) |
|---|--|
| Acero<br>Pórticos dúctiles con uniones resistentes a momentos.  | 9.5  |
| Otras estructuras de acero: Arriostres Excéntricos. Arriostres en Cruz.   | 6.5<br>6.0   |
| Concreto Armado<br>Pórticos <sup>(1)</sup> .<br>Dual <sup>(2)</sup> .<br>De muros estructurales <sup>(3)</sup> .<br>Muros de ductilidad limitada <sup>(4)</sup> . | 8<br>7<br>6<br>4   |
| Albañilería Armada o Confinada <sup>(5)</sup> .   | 3  |
| Madera (Por esfuerzos admisibles)   | 7  |

1. Por lo menos el 80% del cortante en la base actúa sobre las columnas de los pórticos que cumplan los requisitos de la NTE E.060 Concreto Armado. En caso se tengan muros estructurales, estos deberán diseñarse para resistir una fracción de la acción sísmica total de acuerdo con su rigidez.
2. Las acciones sísmicas son resistidas por una combinación de pórticos y muros estructurales. Los pórticos deberán ser diseñados para tomar por lo menos 25% del cortante en la base. Los muros estructurales serán diseñados para las fuerzas obtenidas del análisis según Artículo 16 (16.2)
3. Sistema en el que la resistencia sísmica está dada predominantemente por muros estructurales sobre los que actúa por lo menos el 80% del cortante en la base.
4. Edificación de baja altura con alta densidad de muros de ductilidad limitada.
5. Para diseño por esfuerzos admisibles el valor de R será 6

### **1.2.5.8. Desplazamientos Laterales**

#### **Desplazamientos Laterales Permisibles**

El máximo desplazamiento relativo de entrepiso, calculado según el Artículo 16 (16.4), no deberá exceder la fracción de la altura de entrepiso que se indica en la Tabla N° 05.

**Tabla 05: Límites para Desplazamiento Lateral de entrepiso**

|  |                                    |
|--|------------------------------------|
| Estos límites no son aplicables a naves industriales |                                    |
| Material predominante                                | (D <sub>i</sub> /h <sub>ei</sub> ) |
| Concreto Armado                                      | 0.007                              |
| Acero  | 0.010                              |
| Albañilería  | 0.005                              |
| Madera   | 0.010                              |

### **1.2.5.9. Análisis de edificios.**

**a. Solicitaciones Sísmicas y Análisis:** En concordancia con los principios de diseño sismorresistente del Artículo 3, se acepta que las edificaciones tendrán incursiones inelásticas frente a solicitudes sísmicas severas. Por tanto las solicitudes sísmicas de diseño se consideran como una fracción de la solicitud sísmica máxima elástica. El análisis podrá desarrollarse usando las solicitudes sísmicas reducidas con un modelo de comportamiento elástico para la estructura<sup>25</sup>.

**b. Modelos para Análisis de Edificios** El modelo para el análisis deberá considerar una distribución espacial de masas y rigidez que sean adecuadas para calcular los aspectos más significativos del comportamiento dinámico de la estructura. Para edificios en los que se pueda razonablemente suponer que los sistemas de piso funcionan como diafragmas rígidos, se podrá usar un modelo

<sup>25</sup> Reglamento Nacional de Edificaciones Norma E030, pag.211

con masas concentradas y tres grados de libertad por diafragma, asociados a dos componentes ortogonales de traslación horizontal y una rotación. En tal caso, las deformaciones de los elementos deberán compatibilizarse mediante la condición de diafragma rígido y la distribución en planta de las fuerzas horizontales deberá hacerse en función a las rigideces de los elementos resistentes. Deberá verificarse que los diafragmas tengan la rigidez y resistencia suficientes para asegurar la distribución mencionada, en caso contrario, deberá tomarse en cuenta su flexibilidad para la distribución de las fuerzas sísmicas. Para los pisos que no constituyan diafragmas rígidos, los elementos resistentes serán diseñados para las fuerzas horizontales que directamente les corresponde<sup>26</sup>.

**c. Peso de la Edificación** El peso ( $P$ ), se calculará adicionando a la carga permanente y total de la Edificación un porcentaje de la carga viva o sobrecarga que se determinará de la siguiente manera:

Desplazamientos Laterales Los desplazamientos laterales se calcularán multiplicando por 0,75R los resultados obtenidos del análisis lineal y elástico con las solicitudes sísmicas reducidas. Para el cálculo de los desplazamientos laterales no se considerarán los valores mínimos de C/R indicados en el Artículo 17 (17.3) ni el cortante mínimo en la base especificado en el Artículo 18 (18.2 d)<sup>27</sup>

**d. Desplazamientos Laterales** Los desplazamientos laterales se calcularán multiplicando por 0,75R los resultados obtenidos del análisis lineal y elástico con las solicitudes sísmicas reducidas. Para el cálculo de los desplazamientos laterales no se considerarán los valores mínimos de C/R indicados en el Artículo 17 (17.3) ni el cortante mínimo en la base especificado en el Artículo 18 (18.2 d)<sup>28</sup>.

---

<sup>26</sup> Reglamento Nacional de Edificaciones Norma E030, pag.211

<sup>27</sup> Reglamento Nacional de Edificaciones Norma E030, pag.211

<sup>28</sup> Reglamento Nacional de Edificaciones Norma E030, pag.211

**e. Efectos de Segundo Orden (P-Delta)** Los efectos de segundo orden deberán ser considerados cuando produzcan un incremento de más del 10 % en las fuerzas internas. Para estimar la importancia de los efectos de segundo orden, podrá usarse para cada nivel el siguiente cociente como índice de estabilidad:

$$Q = \frac{N_i * \Delta_i}{V_i * h e_i * R}$$

Los efectos de segundo orden deberán ser tomados en cuenta cuando  $Q > 0,1$ <sup>29</sup>

**f. Solicitaciones Sísmicas Verticales.** Estas solicitudes se considerarán en el diseño de elementos verticales, en elementos post o pre tensados y en los voladizos o salientes de un edificio<sup>30</sup>

#### 1.2.5.10. Análisis Estático

Este método representa las solicitudes sísmicas mediante un conjunto de fuerzas horizontales actuando en cada nivel de la edificación. Debe emplearse sólo para edificios sin irregularidades y de baja altura según se establece en el Artículo 14 (14.2)<sup>31</sup>

##### a. Fuerza Cortante en la Base

La fuerza cortante total en la base de la estructura, correspondiente a la dirección considerada, se determinará por la siguiente expresión:

$$V = \frac{ZUCS}{R} * P$$

debiendo considerarse para C/R el siguiente valor mínimo:

$$\frac{C}{R} \geq 0.125$$

##### b. Distribución de la Fuerza Sísmica en Altura

---

<sup>29</sup> Reglamento Nacional de Edificaciones Norma E030, pag.212

<sup>30</sup> Reglamento Nacional de Edificaciones Norma E030, pag.212

<sup>31</sup> Reglamento Nacional de Edificaciones Norma E030, pag.212

Si el período fundamental T, es mayor que 0,7 s, una parte de la fuerza cortante V, denominada Fa, deberá aplicarse como fuerza concentrada en la parte superior de la estructura. Esta fuerza Fa se determinará mediante la expresión:

$$F_a = 0.07 * T * V \leq 0.15 * V$$

Donde el período T en la expresión anterior será el mismo que el usado para la determinación de la fuerza cortante en la base. El resto de la fuerza cortante, es decir ( $V - F_a$ ) se distribuirá entre los distintos niveles, incluyendo el último, de acuerdo a la siguiente expresión<sup>32</sup>:

$$F_i = \frac{P_i * h_i}{\sum_{j=1}^n P_j * h_j} * (V - F_a)$$

### c. Efectos de Torsión.

Se supondrá que la fuerza en cada nivel ( $F_i$ ) actúa en el centro de masas del nivel respectivo y debe considerarse además el efecto de excentricidades accidentales como se indica a continuación. Para cada dirección de análisis, la excentricidad accidental en cada nivel ( $e_i$ ), se considerará como **0,05** veces la dimensión del edificio en la dirección perpendicular a la de la acción de las fuerzas. En cada nivel además de la fuerza actuante, se aplicará el momento accidental denominado ***Mti*** que se calcula como:

$$M_{ti} = \pm F_i * e$$

Se puede suponer que las condiciones más desfavorables se obtienen considerando las excentricidades accidentales con el mismo signo en todos los niveles. Se considerarán únicamente los incrementos de las fuerzas horizontales no así las disminuciones<sup>33</sup>.

---

<sup>32</sup> Reglamento Nacional de Edificaciones Norma E030, pag.212

<sup>33</sup> Reglamento Nacional de Edificaciones Norma E030, pag.212

#### **d. Fuerzas Sísmicas Verticales**

La fuerza sísmica vertical se considerará como una fracción del peso. Para las zonas 3 y 2 esta fracción será de 2/3 Z. Para la zona 1 no será necesario considerar este efecto<sup>34</sup>.

##### **1.2.5.11. Análisis Dinámico**

El análisis dinámico de las edificaciones podrá realizarse mediante procedimientos de combinación espectral o por medio de análisis tiempo-historia. Para edificaciones convencionales podrá usarse el procedimiento de combinación espectral; y para edificaciones especiales deberá usarse un análisis tiempo-historia<sup>34</sup>.

###### **A. Análisis por combinación modal espectral.**

###### **a. Modos de Vibración.**

Los periodos naturales y modos de vibración podrán determinarse por un procedimiento de análisis que considere apropiadamente las características de rigidez y la distribución de las masas de la estructura<sup>34</sup>.

###### **b. Aceleración Espectral.**

Para cada una de las direcciones horizontales analizadas se utilizará un espectro inelástico de pseudo-aceleraciones definido por:

$$S_a = \frac{ZUCS}{R} * g$$

Para el análisis en la dirección vertical podrá usarse un espectro con valores iguales a los 2/3 del espectro empleado para las direcciones horizontales<sup>34</sup>.

### c. Criterios de Combinación

Mediante los criterios de combinación que se indican, se podrá obtener la respuesta máxima esperada ( $r$ ) tanto para las fuerzas internas en los elementos componentes de la estructura, como para los parámetros globales del edificio como fuerza cortante en la base, cortantes de entrepiso, momentos de volteo, desplazamientos totales y relativos de entrepiso.

La respuesta máxima elástica esperada ( $r$ ) correspondiente al efecto conjunto de los diferentes modos de vibración empleados ( $n$ ) podrá determinarse usando la siguiente expresión.

$$r = 0.25 * \sum_{i=1}^m |r_i| + 0.75 * \sqrt{\sum_{i=1}^m r_i^2}$$

Alternativamente, la respuesta máxima podrá estimarse mediante la combinación cuadrática completa de los valores calculados para cada modo.

En cada dirección se considerarán aquellos modos de vibración cuya suma de masas efectivas sea por lo menos el 90% de la masa de la estructura, pero deberá tomarse en cuenta por lo menos los tres primeros modos predominantes en la dirección de análisis<sup>34</sup>.

### d. Fuerza Cortante Mínima en la Base

Para cada una de las direcciones consideradas en el análisis, la fuerza cortante en la base del edificio no podrá ser menor que el 80 % del valor calculado según el Artículo 17 (17.3) para estructuras regulares, ni menor que el 90 % para estructuras irregulares.

---

<sup>34</sup> Reglamento Nacional de Edificaciones Norma E030, pag.213

Si fuera necesario incrementar el cortante para cumplir los mínimos señalados, se deberán escalar proporcionalmente todos los otros resultados obtenidos, excepto los desplazamientos<sup>35</sup>.

#### e. Efectos de Torsión

La incertidumbre en la localización de los centros de masa en cada nivel, se considerará mediante una excentricidad accidental perpendicular a la dirección del sismo igual a 0,05 veces la dimensión del edificio en la dirección perpendicular a la dirección de análisis. En cada caso deberá considerarse el signo más desfavorable<sup>36</sup>.

### B. Análisis Tiempo-Historia

El análisis tiempo historia se podrá realizar suponiendo comportamiento lineal y elástico y deberán utilizarse no menos de cinco registros de aceleraciones horizontales, correspondientes a sismos reales o artificiales. Estos registros deberán normalizarse de manera que la aceleración máxima corresponda al valor máximo esperado en el sitio.

Para edificaciones especialmente importantes el análisis dinámico tiempo-historia se efectuará considerando el comportamiento inelástico de los elementos de la estructura<sup>37</sup>.

#### 1.2.6. Criterios de Estructuración y Diseño:

Mientras más compleja es la estructura, más difícil resulta predecir su comportamiento sísmico. Por esta razón, es aconsejable que la estructuración sea lo más simple y limpia posible, de manera que la idealización necesaria para su análisis sísmico se acerque lo más posible a lo real. Debe además tratar de

<sup>35</sup> Reglamento Nacional de Edificaciones Norma E030, pag.213

<sup>36</sup> Reglamento Nacional de Edificaciones Norma E030, pag.213

<sup>37</sup> Reglamento Nacional de Edificaciones Norma E030, pag.213

evitarse que los elementos no estructurales distorsionen la distribución de fuerzas considerada, pues se generan fuerzas en elementos que no fueron diseñadas para esas condiciones.

Los principales criterios que es necesario tomar en cuenta para lograr una estructura sismo-resistente, son:

- a. Simplicidad y simetría.
- b. Resistencia y ductilidad.
- c. Hiperestaticidad y monolitismo.
- d. Uniformidad y continuidad de la estructura.
- e. Rigidez lateral.
- f. Existencia de losas que permitan considerar a la estructura como una unidad (diafragma rígido)<sup>38</sup>

#### **1.2.7. Predimensionamiento de elementos estructurales.**

##### **A. Predimensionamiento de losas.**

**1. Aligerados.** Puede ser dimensionado considerando los siguientes criterios.

$h = 17 \text{ cm}$ . luces menores a 4.0 mt.

$h = 20 \text{ cm}$ . luces comprendidas entre 4.0 y 5.5 mt.

$h = 25 \text{ cm}$ . luces comprendidas entre 5.5 y 6.5 mt.

$h = 30 \text{ cm}$ . luces comprendidas entre 6.0 y 7.5 mt<sup>39</sup>.

##### **B. Predimensionamiento de vigas.**

Las vigas se dimensionan generalmente considerando un peralte del orden de 1/10 a 1/12 de la luz libre. El ancho es menos importante que el peralte pudiendo variar entre **0.3 a 0.5 de la altura**. La norma E060 indica que las vigas deben

---

<sup>38</sup> Blanco, A. (1994) 2da. Estructuración y Diseño de Edificaciones de Concreto Armado, Pag.5-13

<sup>39</sup> Blanco, A. (1994) 2da. Estructuración y Diseño de Edificaciones de Concreto Armado, Pag.36

tener un ancho mínimo de 25 cm. para el caso de que estas formen parte de pórticos o elementos sismorresistentes de estructuras de concreto armado<sup>40</sup>.

A continuación dimensionamiento de vigas.

|                        |                                       |
|------------------------|---------------------------------------|
| $L \leq 5.5 \text{ m}$ | 25 x 50 – 30 x 50                     |
| $L \leq 6.5 \text{ m}$ | 25 x 60 – 30 x 60 – 40 x 60           |
| $L \leq 7.5 \text{ m}$ | 25 x 70 – 30 x 70 – 40 x 70 – 50 x 70 |

### C. Predimensionamiento de columnas.

Para edificios aporticados íntegramente, para los cuales el autor recomienda no exceder 3 ó 4 pisos, las columnas deberán dimensionarse mediante alguna estimación del momento de sismo , demostrando la experiencia que se requerirá con un área fluctuante entre 1000 y 2000 cm<sup>2</sup>, salvo que se tenga luces superiores a 7 mt.

Así para este tipo de edificios, se dispondrá de columnas de 35x35, 40x40, 25x50, 30x60, 30x40, 30x50 o circulares de 40 ó 50 cm de diámetro.

Se debe cuidar el peralte de las columnas exteriores de los pórticos principales, pero debe buscarse para la dirección transversal algunas columnas peraltadas. Es muy útil en estos casos las columnas esquineras en forma de “L” las exteriores en forma de “T”, o un mixto de columnas rectangulares con algunas peraltadas en la dirección principal (exteriores) y otras peraltadas en la dirección secundaria (interiores)<sup>41</sup>.

<sup>40</sup> Blanco, A. (1994) 2da. Estructuración y Diseño de Edificaciones de Concreto Armado, Pag.39

<sup>41</sup> Blanco, A. (1994) 2da. Estructuración y Diseño de Edificaciones de Concreto Armado, Pag.42

### **1.2.8. Diseño de elementos estructurales de concreto armado.**

#### **a. Diseño por resistencia.**

En sus inicios se denominó diseño por resistencia última o diseño por rotura (Ultimate Strength Design ó USD), hoy en día se lo conoce con el nombre de diseño por Resistencia (Strength Design method).

Este método es en esencia un diseño por estados límites, con la particularidad que la atención se centra en los estados límites últimos, los estados límites de servicio se verifican luego del diseño del diseño del refuerzo de acero.

El término resistencia hay que entenderlo en un sentido amplio, es aplicable a cualquier solicitud o fuerza de sección, tal como: flexión, cortante, carga axial, torsión, etc. O a combinaciones de estas<sup>42</sup>.

#### **b. Factores de reducción de resistencia-resistencia de diseño.**

Los factores de reducción de resistencia ( $\Phi$ ) afectan las resistencias nominales de las secciones y toman en cuenta las siguientes incertidumbres<sup>43</sup>.

- La variabilidad en la resistencia de los materiales en nuestro caso del concreto y acero.
- Las consecuencias de la falla del elemento dentro de la estructura y las consecuencias de la falla del mismo.
- El tipo de falla del elemento, asociada con la solicitud y el comportamiento de este bajo esa solicitud.

<sup>42</sup> Ottazzi, G. (2003). Apuntes del curso de Concreto Armado 1, pag.60

<sup>43</sup> Ottazzi, G. (2003). Apuntes del curso de Concreto Armado 1, pag.62

**c. Factores de reducción de resistencia de la RNE – Norma E060<sup>44</sup>**

| Factor de Reducción de Resistencia | $\phi$ |
|------------------------------------|--------|
| Flexión sin carga axial            | 0.90   |
| Carga axial de tracción            | 0.90   |
| Carga axial de compresión sunchos  | 0.75   |
| Carga axial de compresión estribos | 0.70   |
| Cortante y torsión                 | 0.85   |
| Aplastamiento en el concreto       | 0.70   |

**d. Factores de carga-resistencia requerida.**

En el diseño por resistencia las cargas de servicio se llevan a una condición extrema o última (de allí el nombre original de diseño por rotura USD) es decir a un nivel de cargas de baja posibilidad de ser excedida durante la vida de la estructura. Para ello se utilizan factores de amplificación o mayoración de cargas<sup>45</sup>.

**e. Factores de carga de la RNE norma E060<sup>46</sup>**

|                                  |  |
|----------------------------------|--|
| Cargas Muertas (CM) y Vivas (CV) | $U = 1,4 \text{ CM} + 1,7 \text{ CV}$  |
| cargas de sismo (CS),            | $U = 1,25 (\text{CM} + \text{CV}) \pm \text{CS}$<br>$U = 0,9 \text{ CM} \pm \text{CS}$ |

**f. La Norma E-020 Cargas.**

Las edificaciones y todas sus partes deberán ser capaces de resistir las cargas que se les imponga como consecuencia de su uso previsto. Estas actuarán en las

<sup>44</sup> ICG Norma E060 (2009) capítulo 9, pag.54

<sup>45</sup> Ottazzi, G. (2008). Apuntes del curso de Concreto Armado 1, pag.64

<sup>46</sup> ICG Norma E060 (2009) capítulo 9, pag.53

combinaciones prescritas y no deben causar esfuerzos ni deformaciones que excedan los señalados para cada material estructural en su Norma de diseño específica.

En ningún caso las cargas empleadas en el diseño serán menores que los valores mínimos establecidos en esta Norma.

Las cargas mínimas establecidas en esta Norma están dadas en condiciones de servicio.

Esta Norma se complementa con la NTE E.030 Diseño Sismorresistente y con las Normas propias de diseño de los diversos materiales estructurales<sup>47</sup>.

#### **g. Diseño de Losas Aligeradas y Vigas**

- Diseño por flexión.**

La ecuación básica para el diseño por resistencia es:

$$\emptyset M_n \geq M_u \dots \text{Ec. (1)}$$

$$M_u = \phi \times b \times d^2 \times f'_c \times \omega (1 - 0.59 \times \omega) \dots \text{Ec. (2)}$$

$$\omega = \frac{\rho \times f_y}{f'_c} \dots \text{Ec. (3)}$$

$$\rho = \frac{A_s}{b \times d} \dots \text{Ec. (4)}$$

Dónde:

$M_u$  : Momento amplificado.

$b$  : Ancho de la cara en compresión.

$d$  : Distancia desde la fibra extrema en compresión hasta el centroide del refuerzo longitudinal en tracción.

$f'_c$  : Resistencia especificada a la compresión del concreto.

---

<sup>47</sup> Reglamento Nacional de Edificaciones (2009) NORMA E020 Pag.200

- $f_y$  : Resistencia especificada a la fluencia del refuerzo.  
 $\omega$  : Índice de refuerzo a tracción.  
 $A_s$  : Área del refuerzo longitudinal no pre-esforzado a tracción.  
 $\rho$  : Cuantía del refuerzo  $A_s$  evaluada sobre el área  $bd$ .

En el caso de vigas con acero en tracción y compresión, el momento último es<sup>48</sup>:

$$Mu = 0.85 \times f'_c \times a \times b \left( d - \frac{a}{2} \right) + A'_s \times f_y \times (d - d')$$

Sabiendo que:

$$a = \frac{(A_s - A'_s)f_y}{0.85 \times f'_c \times b} \dots \text{Ec. (5)}$$

Dónde:

- $Mu$  : Momento amplificado.  
 $a$  : Profundidad del bloque rectangular equivalente de esfuerzos.  
 $b$  : Ancho de la cara en compresión.  
 $d$  : Distancia desde la fibra extrema en compresión hasta el centroide del refuerzo longitudinal en tracción.  
 $d'$  : Distancia desde la fibra extrema en compresión al centroide del refuerzo longitudinal en compresión.  
 $f'_c$  : Resistencia especificada a la compresión del concreto.  
 $f_y$  : Resistencia especificada a la fluencia del refuerzo.  
 $A_s$  : Área del refuerzo longitudinal no pre-esforzado a tracción.  
 $A'_s$  : Área del refuerzo longitudinal a compresión.

---

<sup>48</sup> Ottazzi, G. (2008). Apuntes del curso de Concreto Armado 1, Cap.9-10

La cuantía mínima refuerzo por tracción de las secciones rectangulares y de las secciones en T con el ala en compresión, no será menor de:

$$\rho_{min} = \frac{0.7 \times \sqrt{f'c}}{fy} \dots \text{Ec. (6)}$$

La cuantía máxima considerada es el 75% de la cuantía balanceada, la cuantía balanceada se calcula con la expresión siguiente<sup>49</sup>:

$$\rho_b = \beta_1 \times 0.85 \times \frac{f'c}{fy} \times \left( \frac{6000}{6000 + fy} \right) \dots \text{Ec. (7)}$$

- **Diseño por corte.**

La ecuación básica para el diseño por resistencia es:

$$\emptyset Vn \geq Vu \dots \text{Ec. (8)}$$

El aporte del concreto viene dado por<sup>50</sup>:

$$Vc = 0.53 \times \sqrt{f'c} \times b \times d \dots \text{Ec. (9)}$$

$$Vc \leq 0.93 \times \sqrt{f'c} \times b \times d \dots \text{Ec. (10)}$$

La resistencia que debe proporcionar el refuerzo por corte está dada por:

$$Vs \leq \frac{Vu}{\emptyset} - Vc \dots \text{Ec. (11)}$$

Por tanto el espaciamiento entre estribos se calcula según:

$$s = \frac{Av \cdot fy \cdot d}{Vs} \dots \text{Ec. (12)}$$

Sabiendo que  $Av$  (área de refuerzo de cortante) es igual a 2 veces el área del estribo.

Cuando se requiera la colocación del área mínima de refuerzo de cortante, y cuando la torsión sea despreciada el acero mínimo se calcula mediante:

$$Av_{min} = 0.2 \times \sqrt{f'c} \times \frac{bw \cdot s}{fyt} \dots \text{Ec. (13)}$$

---

<sup>49</sup> Ottazzi, G. (2008). Apuntes del curso de Concreto Armado 1, Cap.9-10

<sup>50</sup> Ottazzi, G. (2008). Apuntes del curso de Concreto Armado 1, Cap.19

$$Av_{min} \leq 3.5 \times \frac{bw \cdot s}{fyt} \dots \text{Ec. (14)}$$

Dónde:

$Av_{min}$  : Área mínima del refuerzo para cortante.

$bw$  : Ancho del alma o diámetro de la sección circular.

$s$  : Espaciamiento medido centro a centro de refuerzo transversal.

$fyt$  : Resistencia especificada a la fluencia del refuerzo transversal.

#### **h. Diseño de Columnas.**

Los elementos verticales que soportan carga axial y flexión (flexo compresión) se les suele denominar columnas.

##### **• Flexión Biaxial.**

En la práctica las columnas sometidas a carga axial y flexión Biaxial, se presentan con más frecuencia que las vigas. Una situación típica es la de las columnas que soportan los efectos de las fuerzas laterales de sismo o viento. En este caso además de la flexión producida por las cargas verticales (de gravedad) alrededor de uno de los ejes principales, se producirá por el sismo o viento flexión alrededor del otro eje principal originando una solicitudación biaxial.

El problema de diseño de columnas en flexión biaxial es complejo numéricamente por la cantidad de iteraciones que es necesario realizar, recuerde que el eje neutro por lo general no es perpendicular a la excentricidad resultante o paralelo al vector momento resultante. Para el diseño normalmente se suele suponer un cierto arreglo de la armadura de refuerzo y el área de acero supuesta se va corriendo hasta lograr que la capacidad de la columna sea adecuada para soportar las solicitudes externas<sup>51</sup>.

---

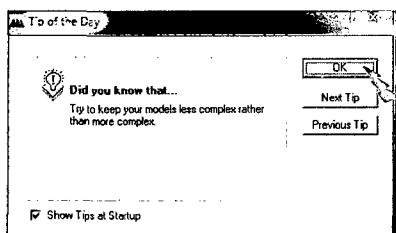

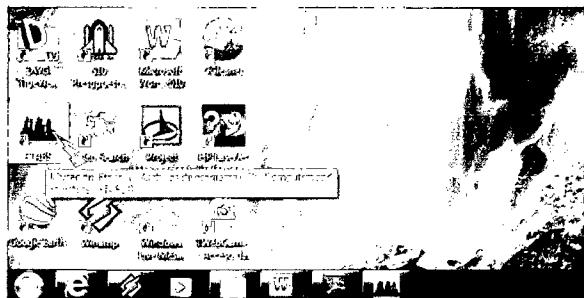

<sup>51</sup> Ottazzi, G. (2008). Apuntes del curso de Concreto Armado 1, pag.389

## CAPITULO II. MODELAMIENTO DE LA ESTRUCTURA

### 2.1 DISEÑO.

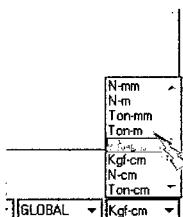

#### 2.1.1. Configurando ETABS.

1. Seleccionamos el icono ETABS del escritorio de la PC e iniciamos el programa.

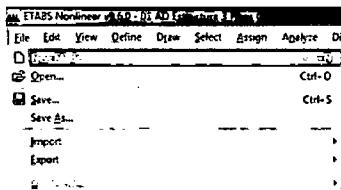

Aparece la ventana del programa y aceptamos el mensaje que aparece.

#### 2. Configuración unidades.

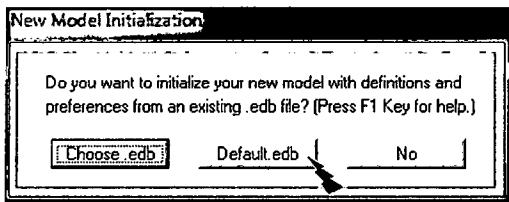

En la parte inferior derecha escogemos las unidades de trabajo (TN-m) es más cómodo trabajar en metros y toneladas.

3. Generando nuevo proyecto. Luego de escoger las unidades generamos un nuevo modelo

## Entramos a File/New Model

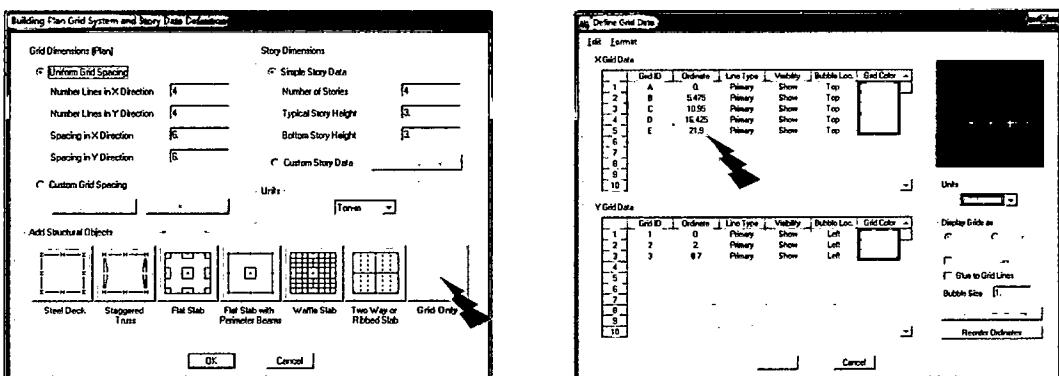

Nos aparece el siguiente mensaje y seleccionamos **Default.edb**

**Choose.edb:** busca archivo para copiar sus preferencias secciones, materiales, combinaciones, etc.

**Default.edb:** modelo predeterminado de ETABS.

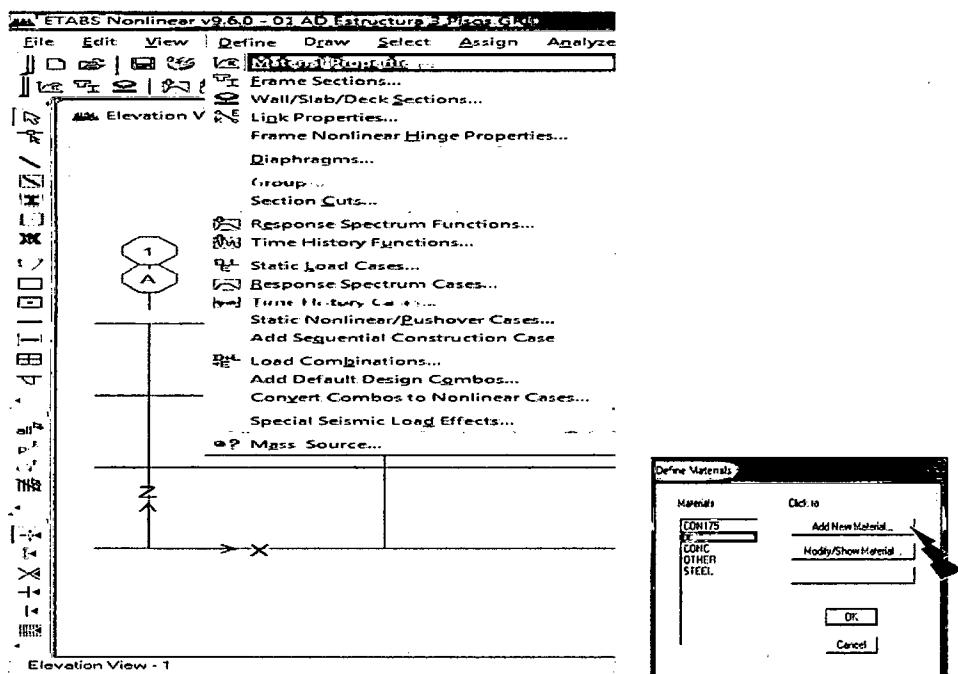

## 4. Configuración de GRID.

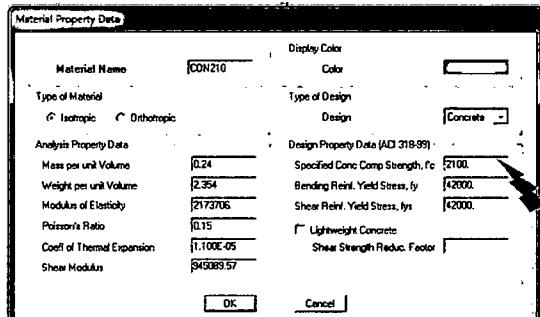

En esta ventana elegimos **Grid Only** el cual nos genera líneas de referencia para idealizar nuestro modelo (líneas de referencia en X, Y, Z).

En esta ventana ingresamos las distancias acumuladas entre ejes de nuestro modelo idealizado.

## 5. Definiendo propiedades de los materiales.

Aquí configuramos los materiales que se van a emplear en el diseño de la estructura.

En este cuadro se ingresan las propiedades mecánicas del material a usar (concreto, acero estructural, ladrillo, adobe, etc.)

**Elementos de la ventana que cambian según el material a definir.**

**Analysis Property Data.**

Mass per unit Volumen (densidad)

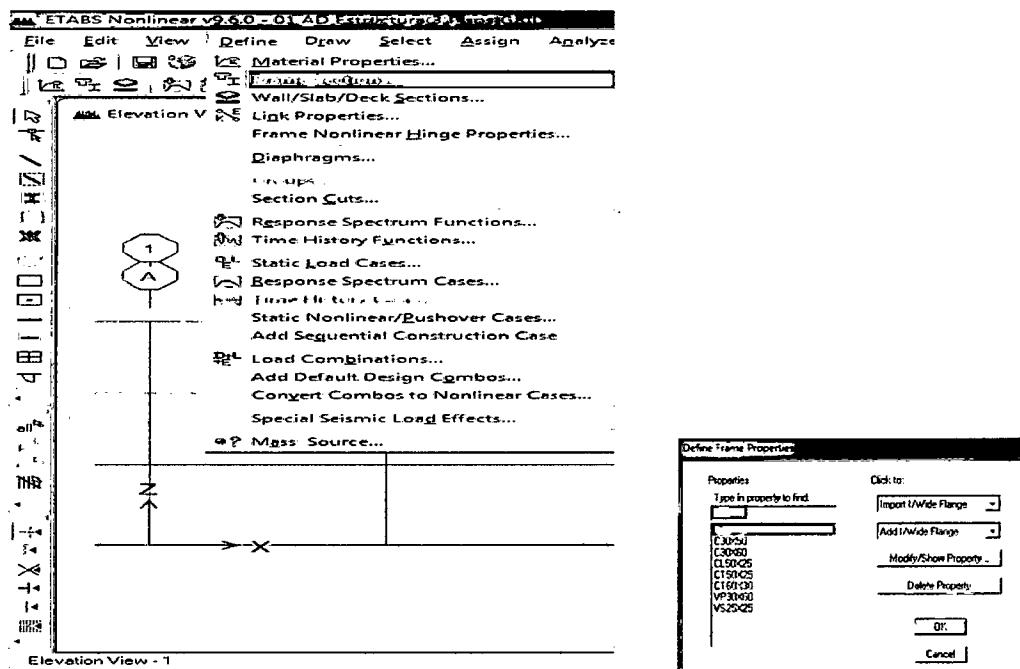

Weight per unit Volume (peso específico)

Modulus of Elasticity (módulo de elasticidad)

Poissons ratio (módulo de Poisson)

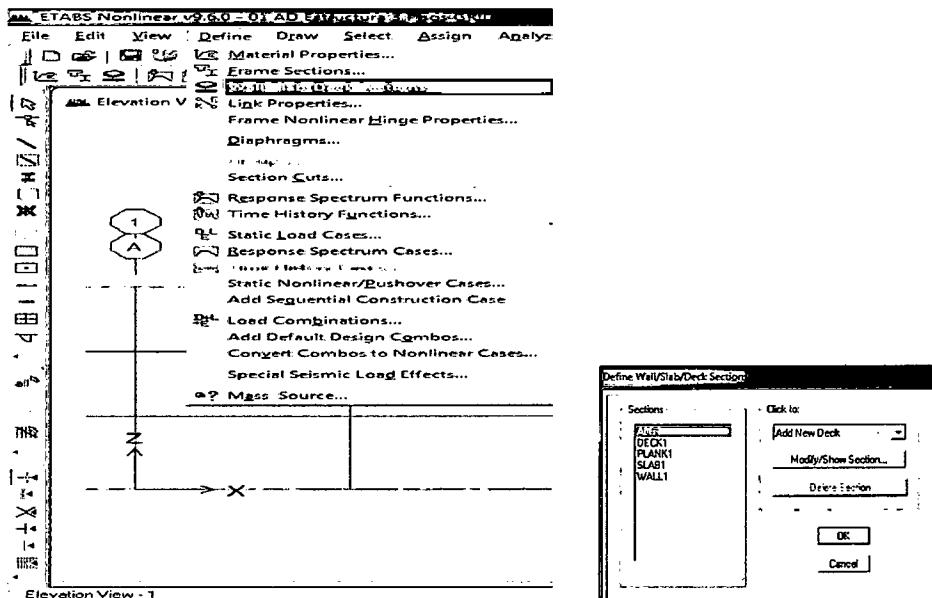

## Shear modulus (módulo de corte)

### 6. Definiendo secciones de elementos estructurales.

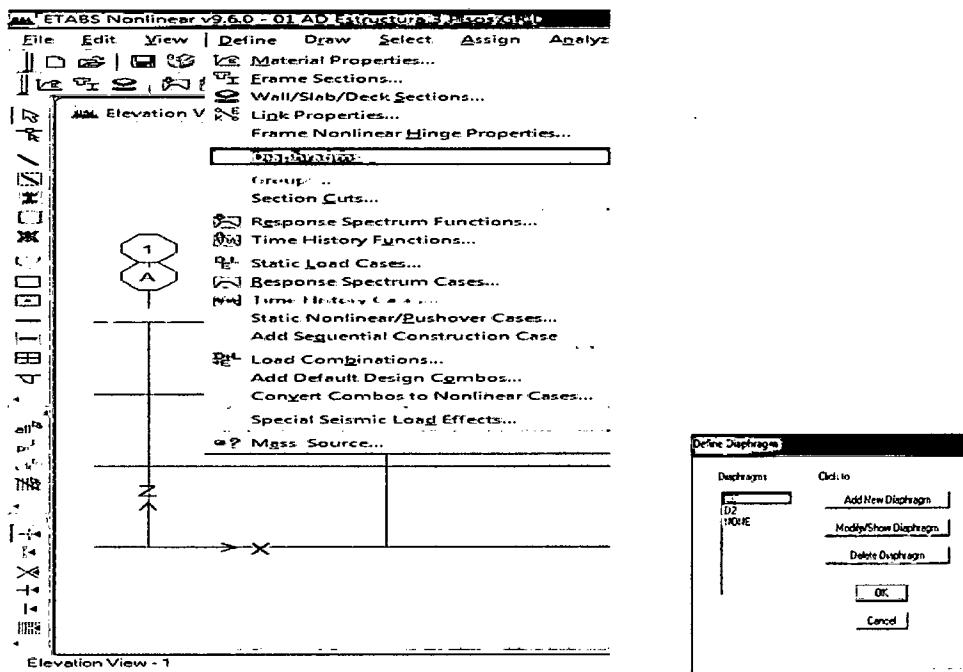

Se define las secciones de las vigas, columnas y se asigna el material de acuerdo a la sección a emplear.

### 7. Definiendo muros, losa aligerada, losa armada en dos direcciones.

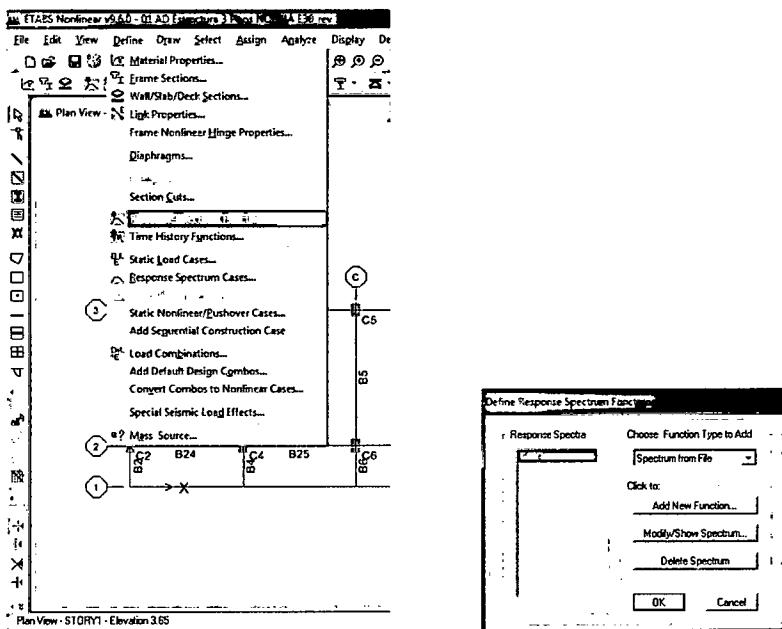

Se define muros, losas aligeradas y armadas en dos direcciones.

## 8. Define diafragmas.

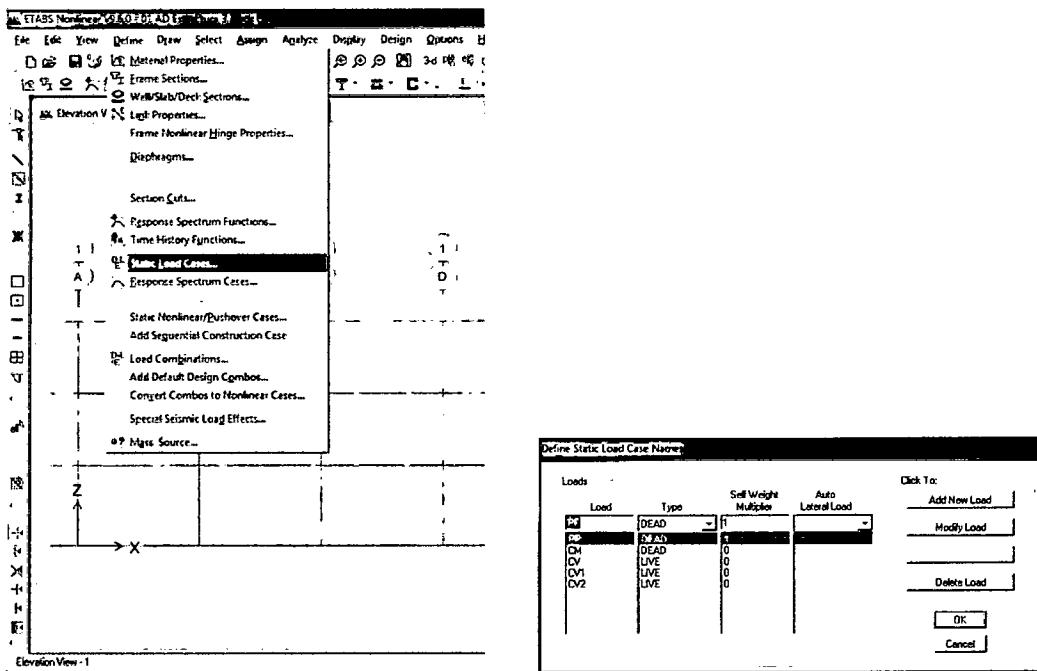

Se define los diafragmas de la estructura se recomienda definir uno para cada nivel.

## 9. Define espectro de diseño.

Se define los espectros de diseño de forma manual o predeterminada para las direcciones X, Y, Z, estos tienen que cumplir con la Norma E030.

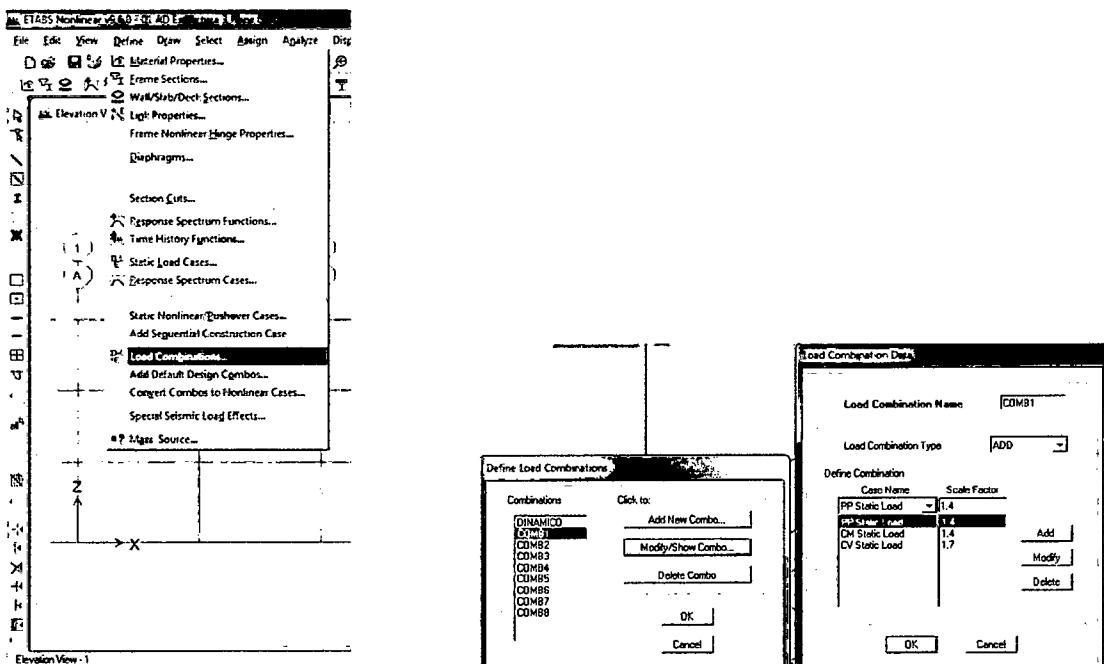

## 10. Define casos estáticos de carga.

Se define las cargas que intervienen como: cargas muertas, vivas, viento, sismo.

Estas deben cumplir con la Norma E020.

## 11. Define combinaciones de carga

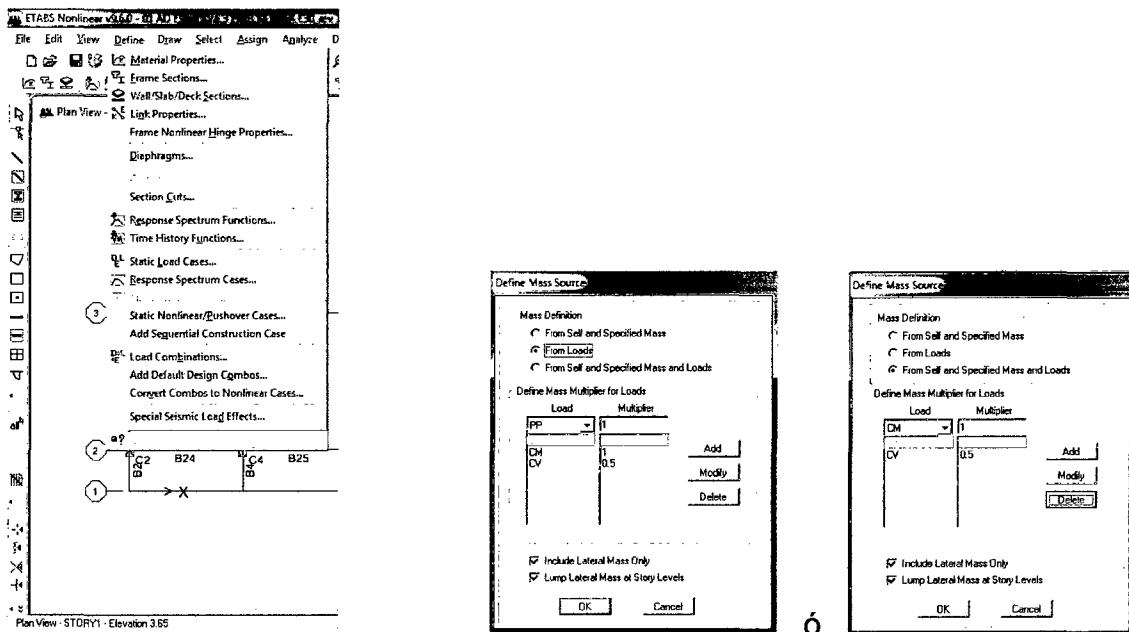

Se define las combinaciones de carga para el análisis de la estructura, las cuales

serán evaluadas en las siguientes configuraciones:

1. Combinación según la NORMA E030 \_  $0.75 \times SRSS + 0.25 \times ABS$
2. Combinación según la NORMA E030 \_ CQC
3. Combinación Predeterminada ETABS \_ CQC

## 12. Define la masa de la estructura.

Según Norma CM factor 1, CV factor 0.5 para edificaciones tipo A ó B.

Se define la masa de la estructura y se tiene 3 modos de definición, los cuales serán evaluados.

- a. ***From Self and Specified Mass.*** Define la masa del peso propio de la estructura y de las masas añadidas.
- b. ***From Loads:*** Define la masa de las cargas. Esta opción puedes especificar las cargas de la cuales se requiere obtener la masa de la estructura. Para cada caso de carga se establece un factor que va de 0 a 1. Es importante destacar que en esta opción se puede incorporar el peso propio DEAD como una carga para que participe como masa.
- c. ***From Self and Specified Mass and Loads:*** Define la masa debido al peso propio de la estructura, esto por masas añadidas y por las cargas impuestas. Para

cada caso de carga incorporado se debe establecer un factor que va de 0 a 1. Es importante destacar que en esta opción no se debe de agregar el peso propio "DEAD" ya que la misma está incluida en la condición ***From Self***.

### **2.1.2. Parámetros del edificio de 3 niveles.**

#### **a. Características de los materiales.**

##### **Concreto.**

$$f'c = 210 \text{ kg/cm}^2.$$

$$Ec = 15000x(f'c)^{1/2}$$

$$\text{Módulo de Poisson } u = 0.15$$

$$\text{Módulo de Rígidez al esfuerzo cortante } Gc = Ec/2*(1+u), \quad Gu = Ec/2.3$$

$$\text{Densidad} = 2400 \text{ kg/m}^3$$

$$\text{Peso específico} = 9.81 \text{ m/s}^2 * 2400 \text{ kg/m}^3 = 23544 \text{ kg/s}^2 \text{ m}^2$$

##### **Acero:**

ASTM A615-GRADO 60

NTP 341.031 GRADO 60

$$f'y_{min} = 4200 \text{ kg/cm}^2. \text{ (fluencia nominal, valor mínimo)}$$

$$f'um_{in} = 6300 \text{ kg/cm}^2. \text{ (esfuerzo máximo o último o resistencia a la tracción)}$$

$$Es = 2'000,000 \text{ kg/cm}^2. \text{ (módulo de elasticidad)}$$

$$Ey = 0.0021 \text{ (deformación en el inicio de fluencia)}$$

$$\text{Coeficiente de dilatación} = 11 \times 10^{-6} \text{ 1/C}^{\circ}.$$

**b. Predimensionamiento:**

**VER ANEXO 01-02 (Plano Planta y cortes)**

**Losas Aligerada:**

Según la tabla 9.1 de la norma E 060 para losas con ambos extremos continuos tenemos.

$$h = \frac{l}{21} = \frac{5.225}{21} = 0.248 \text{ mt}$$

Asumimos un espesor  $h=0.25$  mt.

**Vigas Principales:**

**Peralte de la viga:**

Considerando

$$h = \frac{l}{12} = \frac{6.40}{12} = 0.533 \text{ mt}$$

Asumimos un peralte  $h=0.60$  mt.

**Ancho de la viga:**

Según Norma peruana de concreto armado el ancho mínimo de vigas debe ser 0.25mt para el caso que estas formen parte de pórticos o elementos sismo resistentes.

Asumimos  $b=0.25$ mt.

**Asumiendo una sección de viga principal de 25x60**

**Vigas Secundarias:**

**Peralte de la viga:**

Considerando

$$h = \frac{l}{16} = \frac{5.225}{16} = 0.326 \text{ mt}$$

Asumimos un peralte  $h=0.30$  mt.

**Ancho de la viga:**

Según Norma peruana de concreto armado el ancho mínimo de vigas debe ser 0.25mt para el caso que estas formen parte de pórticos o elementos sismo resistentes.

Asumimos  $b=0.25$ mt.

**Asumiendo una sección de viga Secundaria de 25x30**

**Columnas:**

Peralte de la columna 80% del peralte de la viga principal

$$h = 0.80 \times h(\text{viga principal}) = 0.80 * 0.60 = 0.48$$

Asumiendo  $h=0.50$

Asumiendo un ancho de columna igual al ancho de la viga principal tenemos una **sección de columna de 25x50**

**c. Definición de cargas.**

En la Norma Peruana de cargas E 020 se especifica las cargas estáticas mínimas que se deben adoptar para el diseño estructural.

Para el presente proyecto tenemos las siguientes cargas.

**Cargas muertas:**

• Primer y Segundo Piso

Losa aligerada  $e=0.25$  :  $= 0.240 \text{ ton/m}^2$

Piso terminado :  $= 0.100 \text{ ton/m}^2$

Tabiquería :  $= 0.100 \text{ ton/m}^2$

• Tercer Piso

$W_D$  Primer Piso :  $= 0.340 \text{ ton/m}^2$

$W_D$  Segundo Piso :  $= 0.340 \text{ ton/m}^2$

- **Factor de Amplificación Sísmica.**

$$C = 2.5 \frac{Tp}{T} \leq 2.5$$

Dónde:

$$Tp=0.90$$

$$T = \frac{h_n}{Ct}$$

$$Ct = 35, \quad h_n = 9.75mt$$

Reemplazando.

$$T = 0.2786$$

$$C = 2.5 \frac{Tp}{T} = 2.5 * \frac{0.90}{0.2786} = 8.07 \leq 2.5$$

Asumimos C=2.5

- **Factor de uso e importancia (U)**

El módulo es de un Centro Educativo, con categoría A (edificación esencial) por lo que:

$$U=1.5$$

- **Coeficiente de reducción estructural (R)**

La estructura es regular, no se tiene discontinuidades significativas horizontales o verticales. El sistema estructural sismo resistente está conformado por pórticos de concreto armado.

$$R = 8$$

$$W_D \text{ Tercer Piso} : = 0.340 \text{ ton/m}^2$$

### **Cargas Vivas:**

Según la norma para el presente proyecto tenemos las siguientes cargas.

$$W_L \text{ (aulas)} : = 0.300 \text{ ton/m}^2$$

$$W_L \text{ (corredores)} : = 0.400 \text{ ton/m}^2$$

### **d. Análisis y diseño sísmico del edificio.**

El análisis de la estructura se realizara en el programa ETABS para lo cual se requiere:

#### **e. Parámetros Sísmicos**

A continuación se definen los parámetros necesarios para el análisis estático como para el análisis dinámico de la estructura, según la Norma Sismorresistente E.030 estos parámetros se definieron para ambas direcciones.

- Factor de Zona (Z)**

La estructura se ubica en la ciudad de Cajamarca por lo tanto, pertenece a la zona 3, que le corresponde un factor de zona de:

$$Z=0.40$$

- Tipo de suelo (S) y (Tp)**

Proponemos un tipo de suelo S3 (suelo flexible o suelos con estratos de gran espesor), por lo tanto se tiene:

$$S = 1.40$$

$$Tp = 0.90$$

### Espectro de Pseudo-aceleración.

$$Z = 0.40$$

$$U = 1.50$$

$$S = 1.40 \quad T_p = 0.90$$

$$R = 8$$

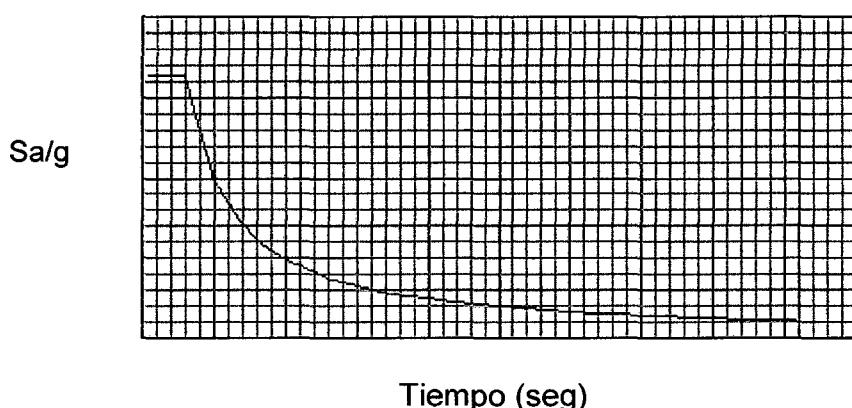

$$C = 2.5$$

$$\frac{Sa}{g} = \frac{Z * U * S * C}{R} = 0.2625$$

Donde  $g$  es la aceleración de la gravedad:  $g = 9.81$  m/seg<sup>2</sup>. Para calcular el coeficiente sísmico  $C$ , se utiliza la fórmula dada por la norma:

$$C = 2.5 \left( \frac{T_p}{T} \right), \quad C \leq 2.5$$

Un gráfico de la pseudo-aceleración como un porcentaje de la gravedad se muestra a continuación:

La entrada de la pseudo-aceleraciones a ser utilizada en el paquete ETABS, se preparó en una tabla que se muestra una parte a continuación:

| T    | Sa/g    | C    |
|------|---------|------|
| 0.10 | 0.26250 | 2.50 |
| 0.28 | 0.26250 | 2.50 |
| 0.90 | 0.26250 | 2.50 |
| 1.00 | 0.23625 | 2.25 |
| 1.50 | 0.15750 | 1.50 |
| 2.00 | 0.11813 | 1.13 |
| 2.50 | 0.09450 | 0.90 |

|       |         |      |
|-------|---------|------|
| 3.00  | 0.07875 | 0.75 |
| 3.50  | 0.06750 | 0.64 |
| 4.00  | 0.05906 | 0.56 |
| 4.50  | 0.05250 | 0.50 |
| 5.00  | 0.04725 | 0.45 |
| 5.50  | 0.04295 | 0.41 |
| 6.00  | 0.03938 | 0.38 |
| 6.50  | 0.03635 | 0.35 |
| 7.00  | 0.03375 | 0.32 |
| 7.50  | 0.03150 | 0.30 |
| 8.00  | 0.02953 | 0.28 |
| 8.50  | 0.02779 | 0.26 |
| 9.00  | 0.02625 | 0.25 |
| 9.50  | 0.02487 | 0.24 |
| 10.00 | 0.02363 | 0.23 |
| 10.50 | 0.02250 | 0.21 |

| 11.50 | 0.02054 | 0.20 |
| 12.00 | 0.01969 | 0.19 |
| 12.50 | 0.01890 | 0.18 |
| 13.00 | 0.01817 | 0.17 |
| 13.50 | 0.01750 | 0.17 |
| 14.00 | 0.01688 | 0.16 |
| 14.50 | 0.01629 | 0.16 |
| 15.00 | 0.01575 | 0.15 |

**f. Características geométricas del edificio.**

**VER ANEXO 03 (Plano de ejes)**

Largo 21.90 m, Ancho = 8.70 m.

Configuración del GRID.

Ejes en “X”.

Eje A = 0.000 m.

Eje B = 5.475 m.

Eje C = 10.950 m.

Eje E = 16.425 m.

Eje F = 21.900 m.

Ejes en “Y”.

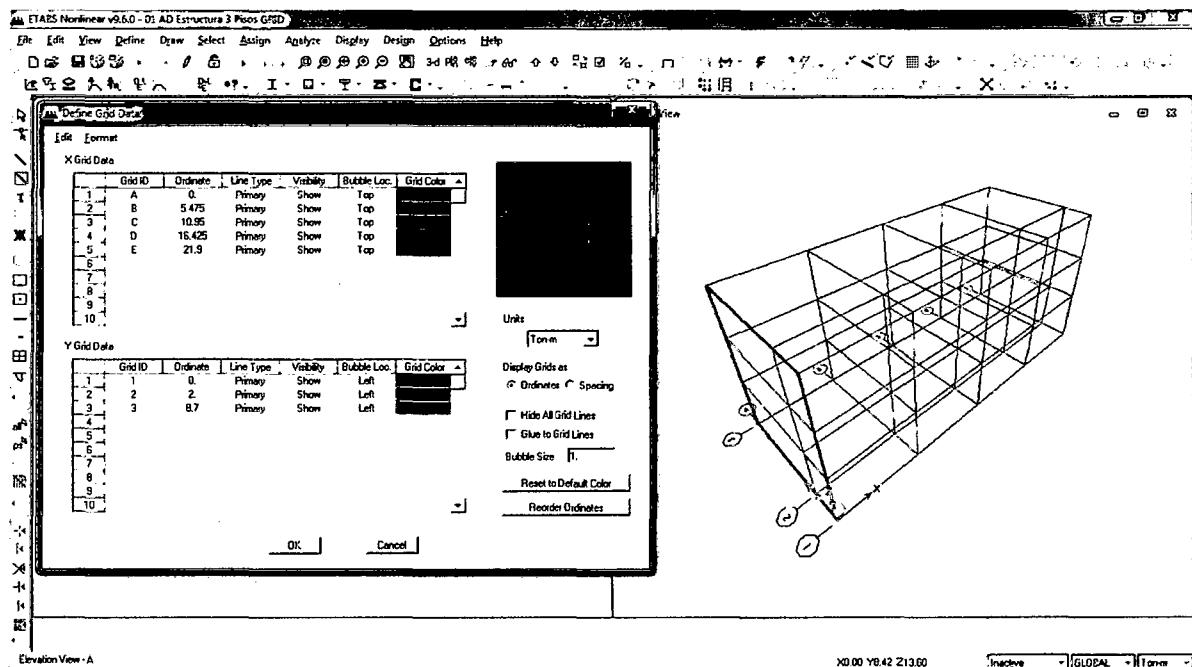

Eje 1 = 0.00 m.

Eje 2 = 2.00 m.

Eje 3 = 8.70 m.

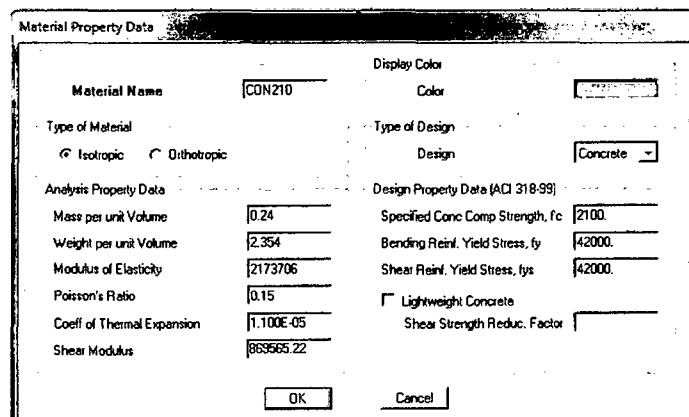

### 2.1.3. Modelamiento del edificio de 3 niveles en ETABS.

#### 1. Configurando el GRID con los valores del edificio.

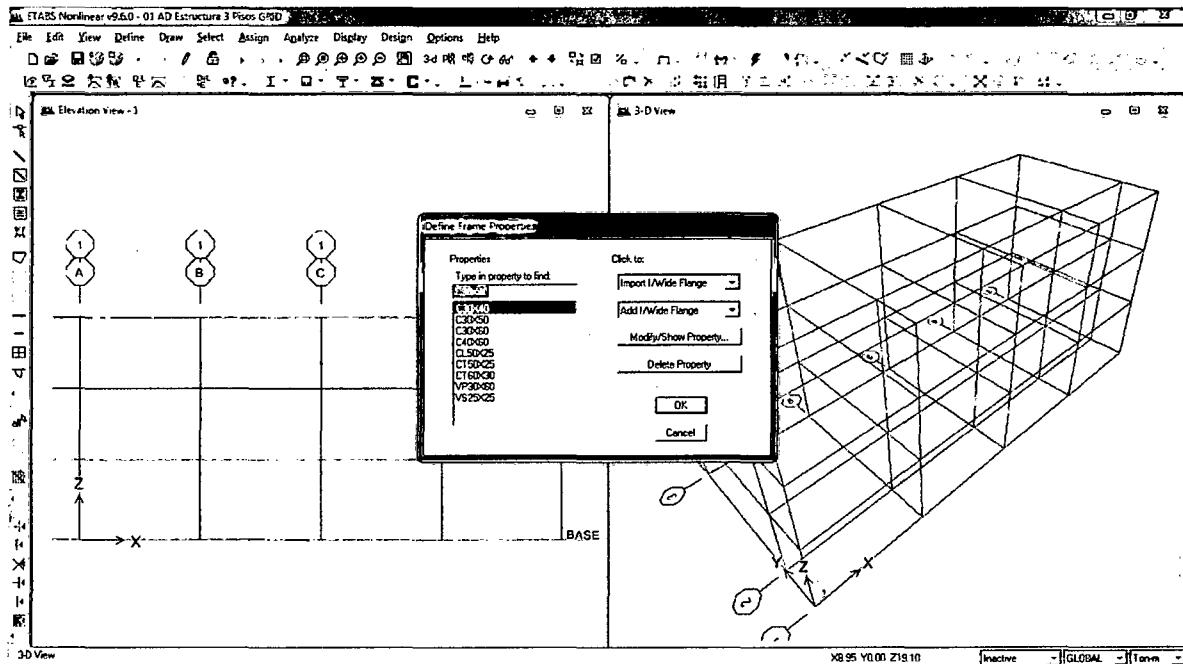

#### 2. Configuración de propiedades del concreto 210 kg/cm<sup>2</sup>.

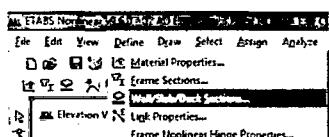

| Configuracion Para Unidades TN-m (ETABS) |              |      |      |
|--|--------------|------|------|
| Mass per unit volume                     | 0.24         | f'c  | 210  |
| Weight per unit volume                   | 2.35         | f'y  | 4200 |
| Modulus of elasticity                    | 2,173,706.00 | f'ys | 4200 |
| Poissons ratio                           | 0.15         |      |      |
| Coeff of thermal expansion               | 1.100E-05    |      |      |
| Shear Modulus                            | 945,089.79   |      |      |

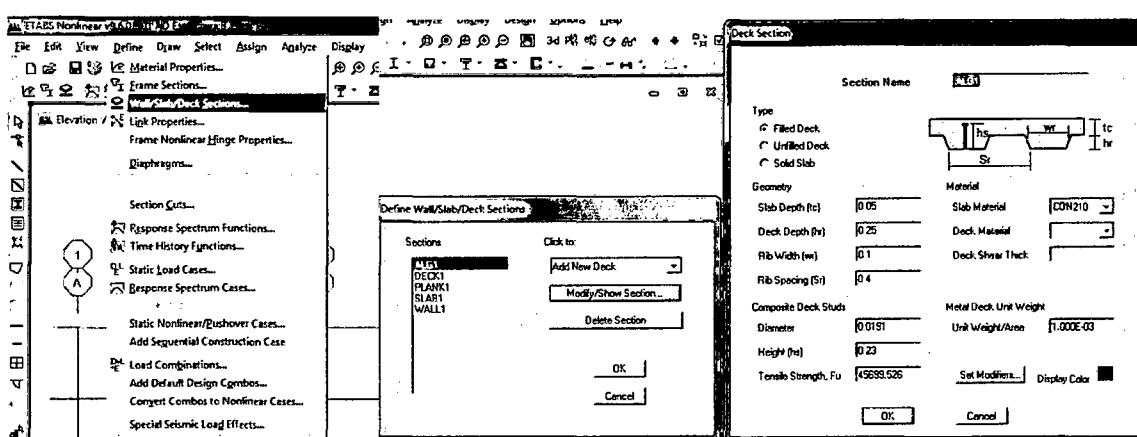

3. Definiendo secciones de vigas y columnas, VP30x60 en los 3 niveles, C40x60 en primer nivel, C30x60 en segundo y tercer nivel, el predimensionamiento VP25x60, C25x50, NO cumple con el análisis dinámico.

4. Definiendo losa aligerada del pre dimensionamiento  $e=25\text{cm}$ .

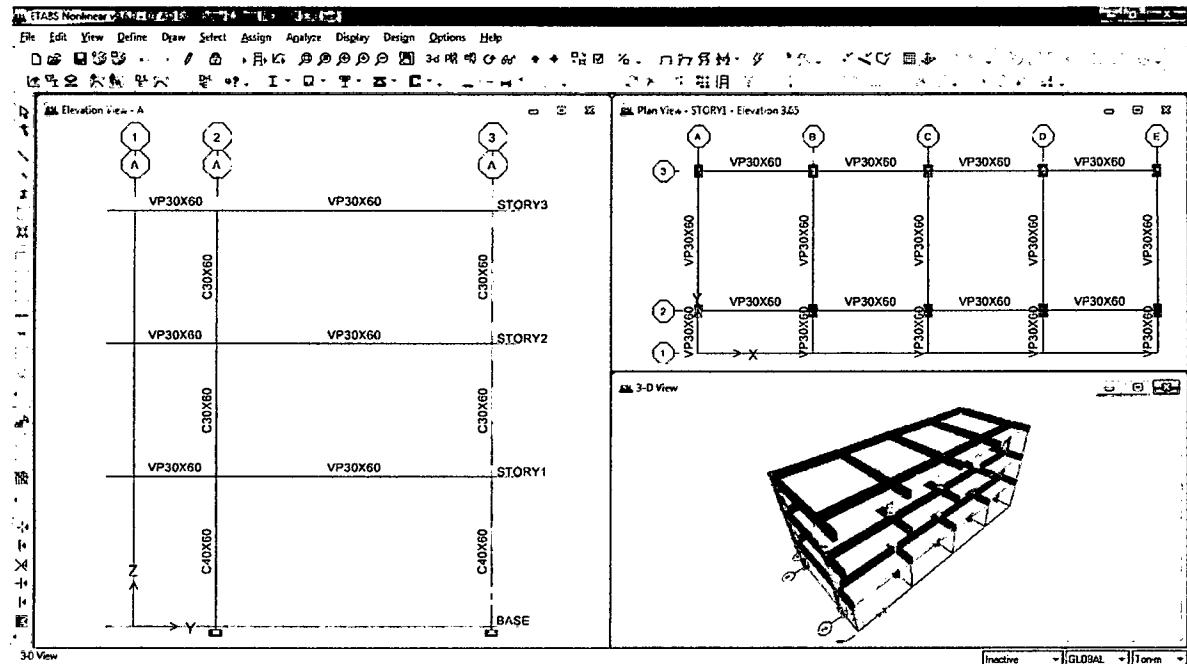

Vamos a Define/Wall-Slab-Deck, seleccionamos Add New Deck y llenamos los siguientes campos para nuestra losa aligerada,  $tc=0.05$ ,  $hr=0.20$ ,  $wr=0.10$ ,  $Sr=0.40$ .

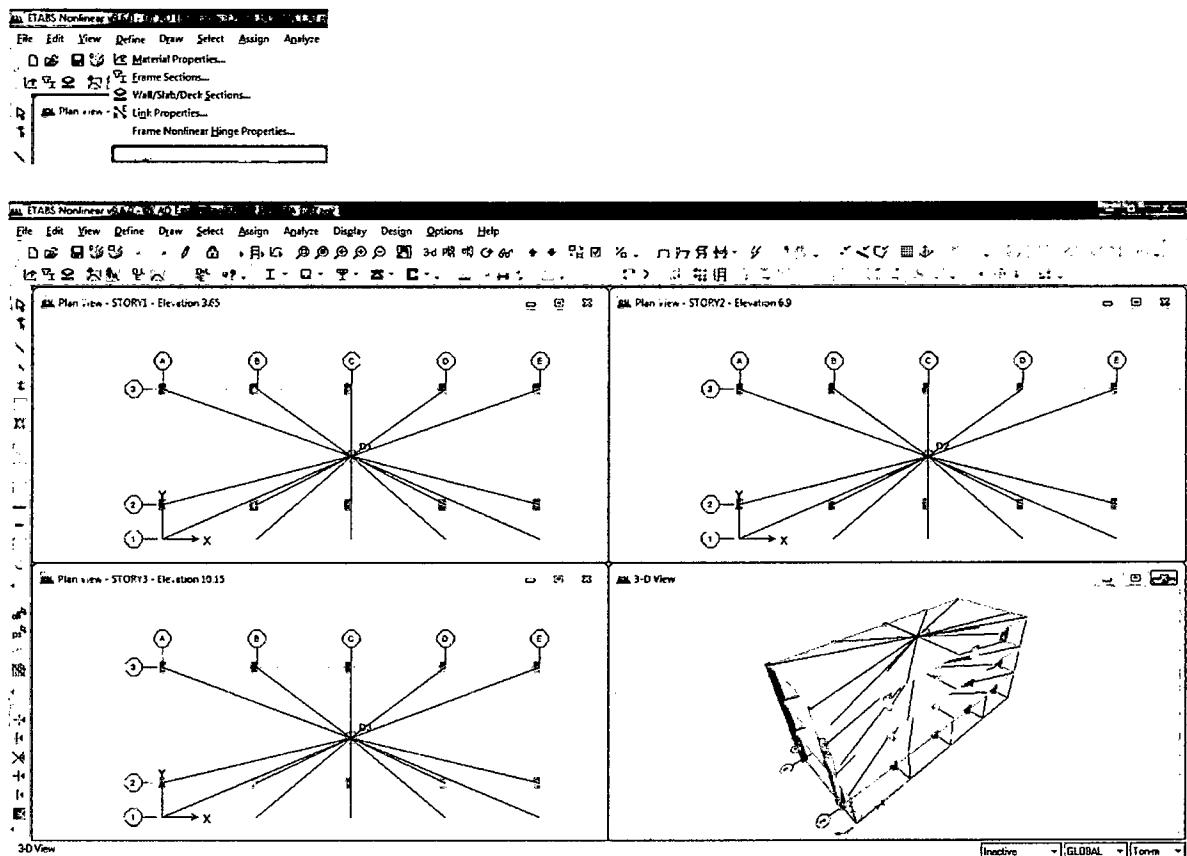

## 5. Asignando vigas, columnas y losas algeradas al modelo.

VP30x60, C30x60, C40x60

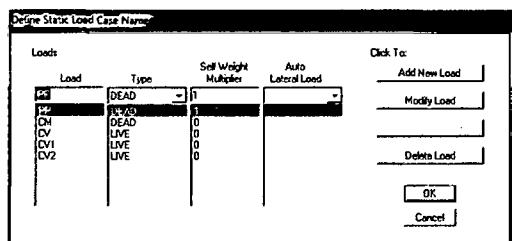

## 6. Definiendo diafragmas rígidos de los 3 niveles. Nivel 01 - D1, Nivel 02 - D2,

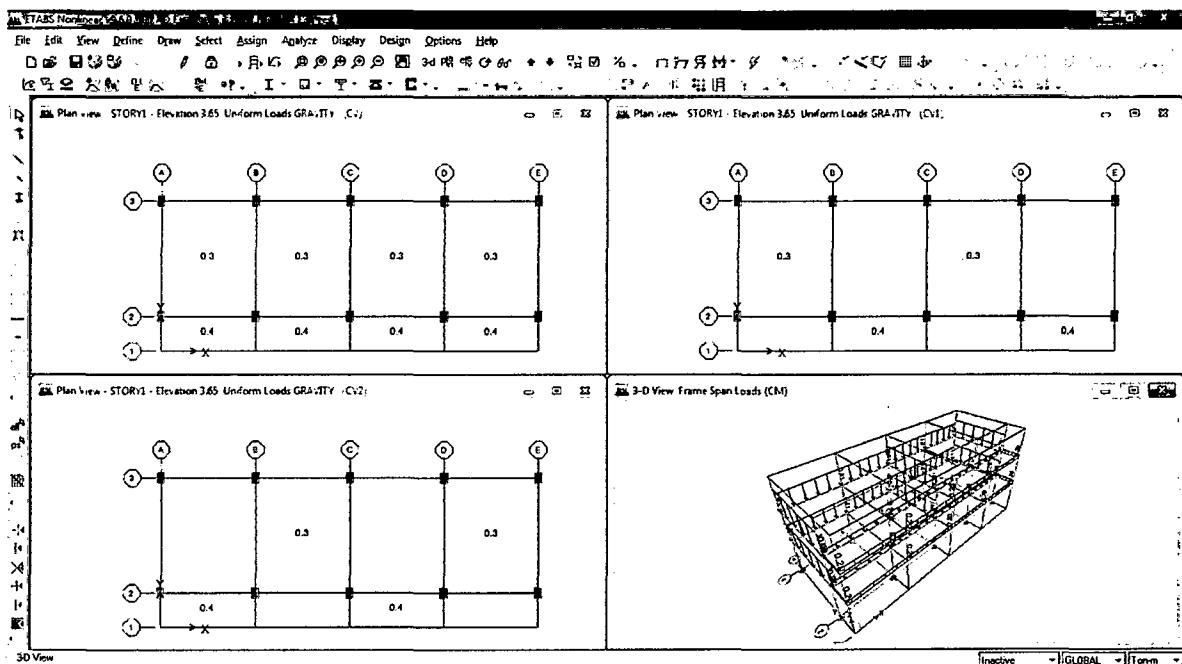

Nivel 03 - D3. Vamos a Define/Diafrags y luego a Assing/Shell-Area/Diafrags

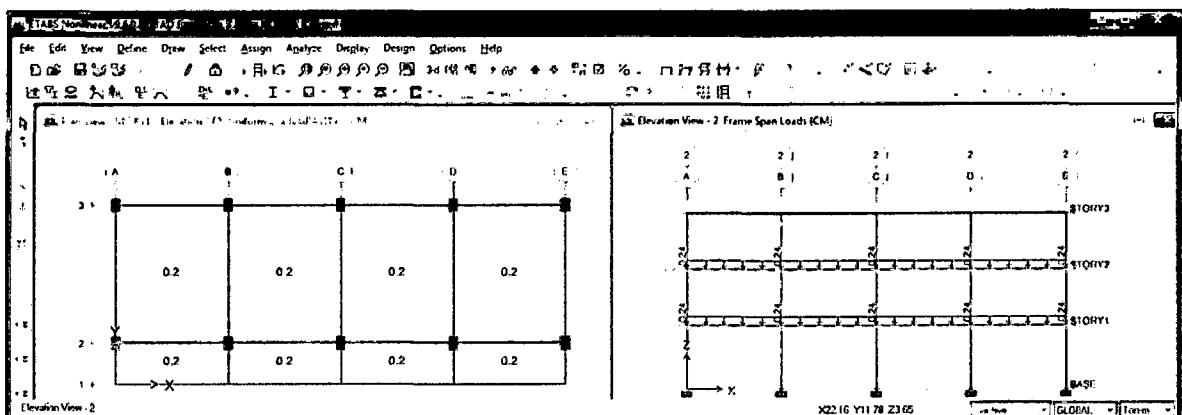

7. Definiendo estados de carga estática CM y CV, los cuales serán cargados según la Norma E020

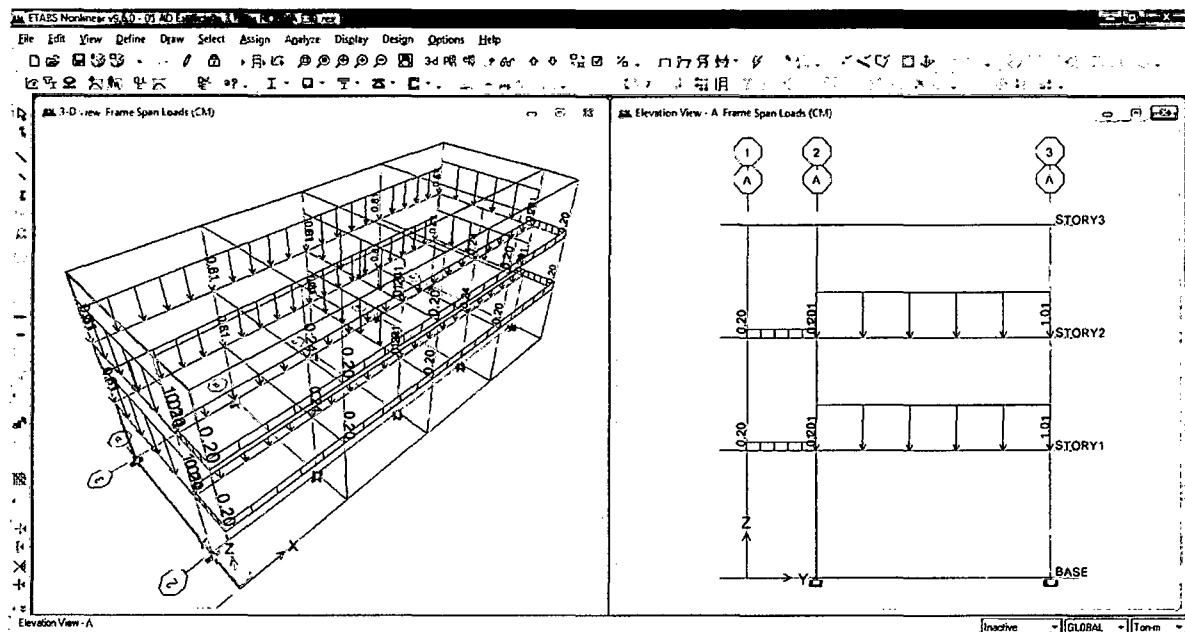

Distribuyendo la carga viva en CV, CV1, CV2, CM para alternarla en forma de tablero de ajedrez y así obtener mayores esfuerzos y momentos.

8. Definiendo CM y CV en las losas de los entrepisos.

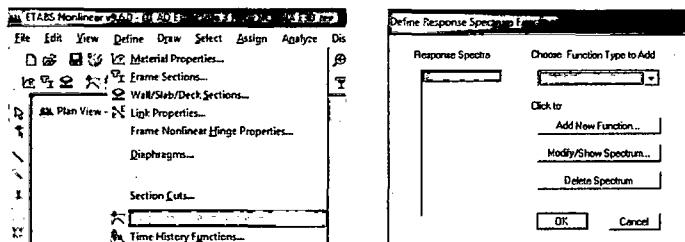

## 9. Cargas Muertas por muros, cargas distribuidas CM.

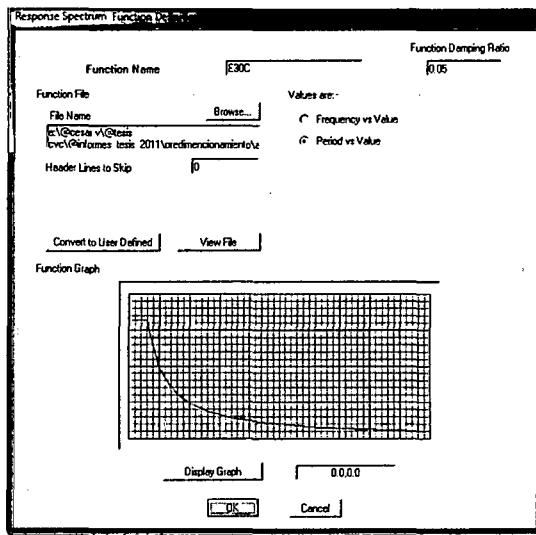

## 10. Definiendo la Función Espectro de diseño SPX, SPY según la norma E030.

Generamos nuestro espectro a partir de nuestro cuadro de pseudo-aceleraciones, calculado para nuestro modelo en estudio.

## 11. Definir método de combinación Modal.

Análisis 01: MODAL COMBINATION. CQC (Combinación Cuadrática Completa)

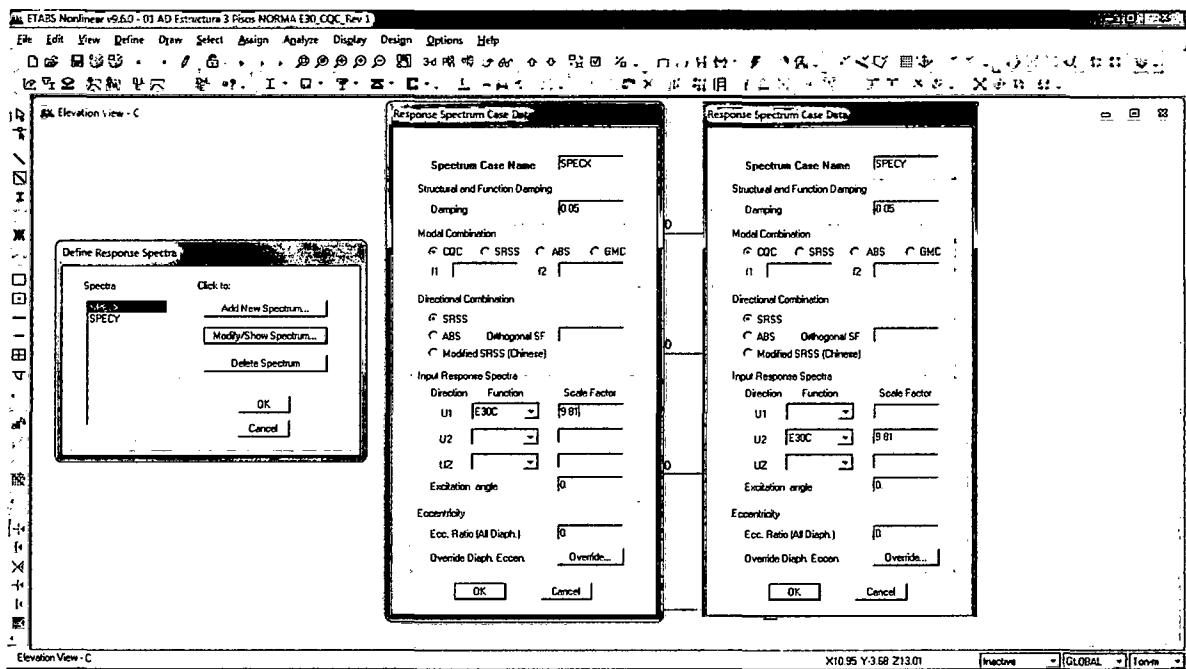

Análisis 02: MODAL COMBINATION. SRSS (Raíz cuadrada de los valores al cuadrado)

Análisis 03: MODAL COMBINATION. ABS (Suma de valores absolutos)

A. Definimos los espectros para Norma E030 (0.75SRSS+0.25ABS)

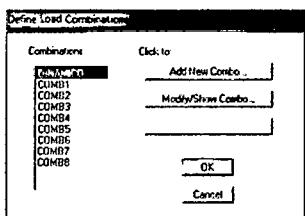

## B. Definimos los espectros para Norma E030 (CQC)

## 12. Definiendo Combinaciones para la NORMA E030 espectro

(0.75SRSS+0.25ABS).

DINAMICO=0.75SRSS+0.25ABS

COMB1=1.4CM+1.4PP+1.7CV

COMB2=1.4CM+1.4PP +1.7CV1

COMB3=1.4CM++1.4PP 1.7CV2

COMB4=1.25(PP+CM+CV+DINAMICO)

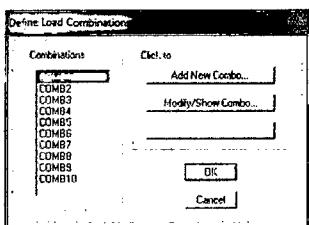

COMB5=1.25(PP+CM+CV1+DINAMICO)

COMB6=1.25(PP+CM+CV2+DINAMICO)

COMB7=0.9(PP+CM+CV)+DINAMICO

COMB8= COMB1+ COMB2+ COMB3+ COMB4+ COMB5+ COMB6+ COMB7

#### 13. Definiendo Combinaciones para la NORMA E030 espectro (CQC).

COMB1=1.4CM+1.4PP+1.7CV

COMB2=1.25(CM+PP +CV)+SPECX

COMB3=1.25(CM+PP +CV1)+SPECX

COMB4=1.25(CM+PP +CV2)+SPECX

COMB5=1.25(CM+PP +CV)+|SPECY

COMB6=1.25(CM+PP +CV1)+SPECY

COMB7=1.25(CM+PP +CV2)+SPECY

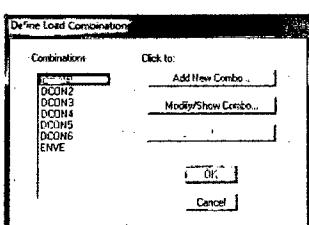

COMB8= 0.90(CM+PP)+SPECX

COMB9= 0.90(CM+PP)+SPECY

COMB10= COMB1+ COMB2+ COMB3+ COMB4+ COMB5+ COMB6+ COMB7+

COMB8+ COMB9

#### 14. Definiendo Combinaciones Norma ACI 318-99 espectro (CQC)

COMB1=1.4CM+1.4PP

COMB2=1.4CM+1.4PP +1.7CV

COMB3=1.33(CM+PP) +1.275CV+1.40SPECX

COMB4=1.33(CM+PP) +1.275CV+1.40SPECY

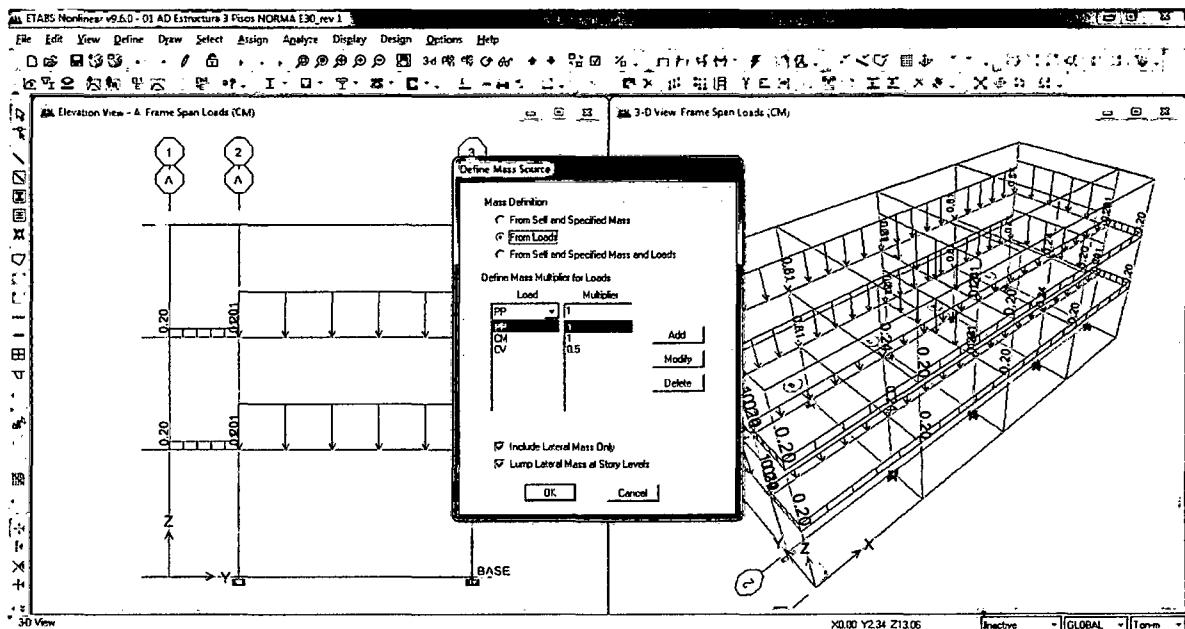

COMB5=0.614(CM+PP) +1.43SPECX

COMB6=0.614(CM+PP) +1.43SPECY

ENVE= COMB1+ COMB2+ COMB3+ COMB4+ COMB5+ COMB6

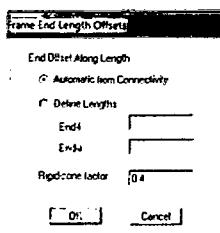

## 15. Definiendo la masa de la estructura Según NORMA E030.

Peso = 1.0xCM + 0.5xCV

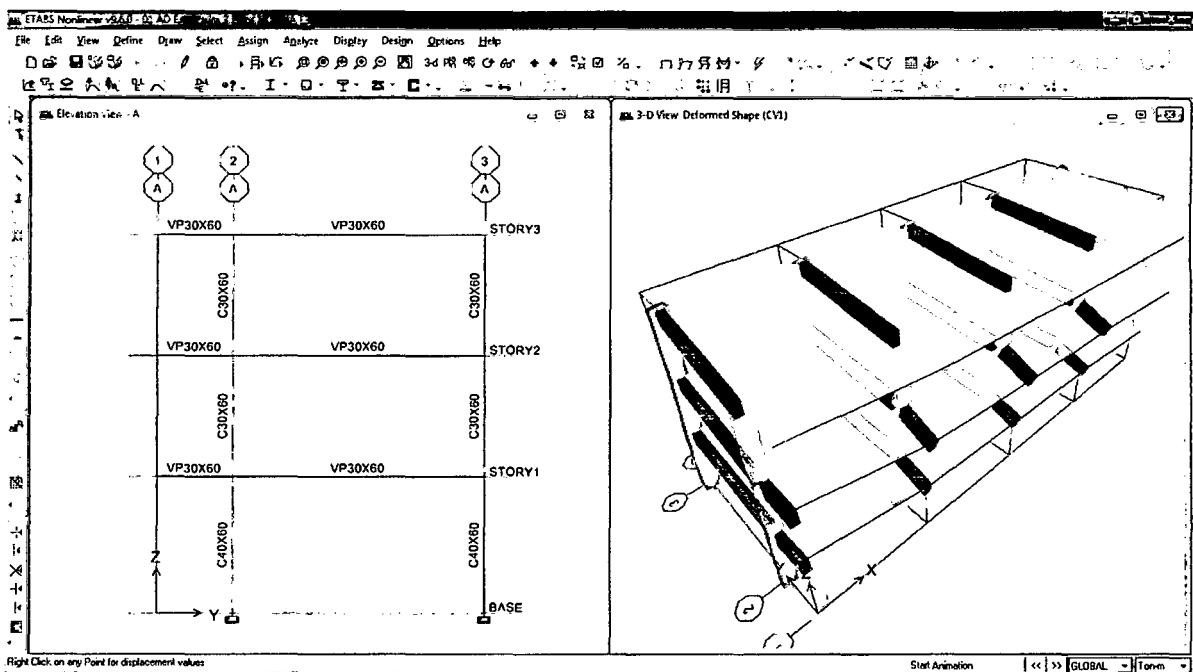

Si usamos para el análisis del edificio **From Loads** ó **From Self and Specified Mass and Loads**, en ambos casos obtendremos el mismo resultado en el dimensionamiento de acero en estructuras de concreto armado.

16. Luego de definir la masa de la estructura se procede a seleccionar todos los elementos del modelo y procedemos a definiendo Factor de Zona 0.4 y cálculo de los momentos en las caras.

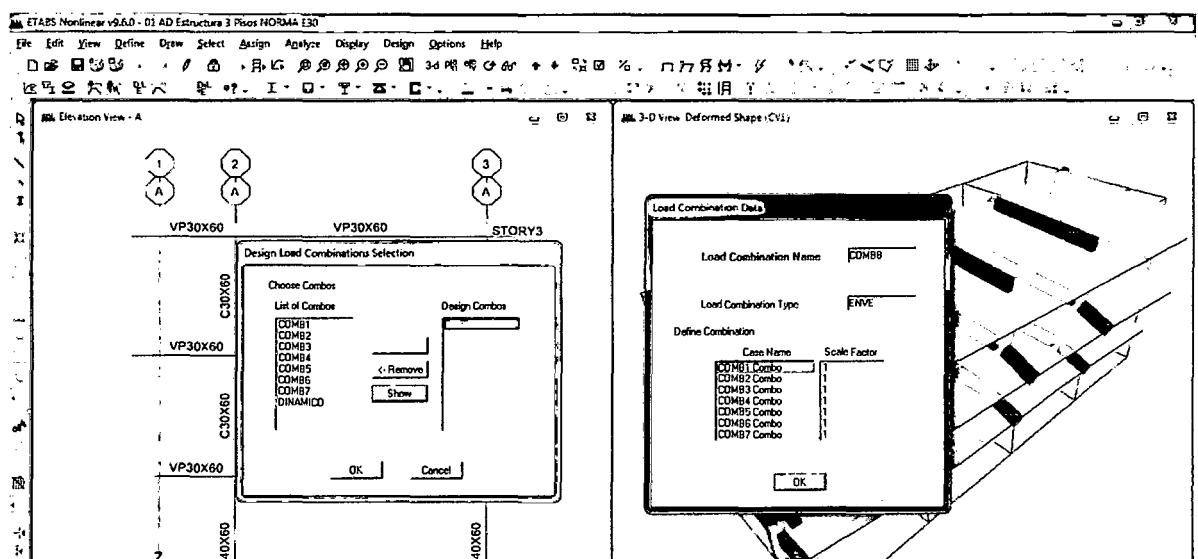

17. Ejecutar el programa, presionar F5 para ejecutar el programa.

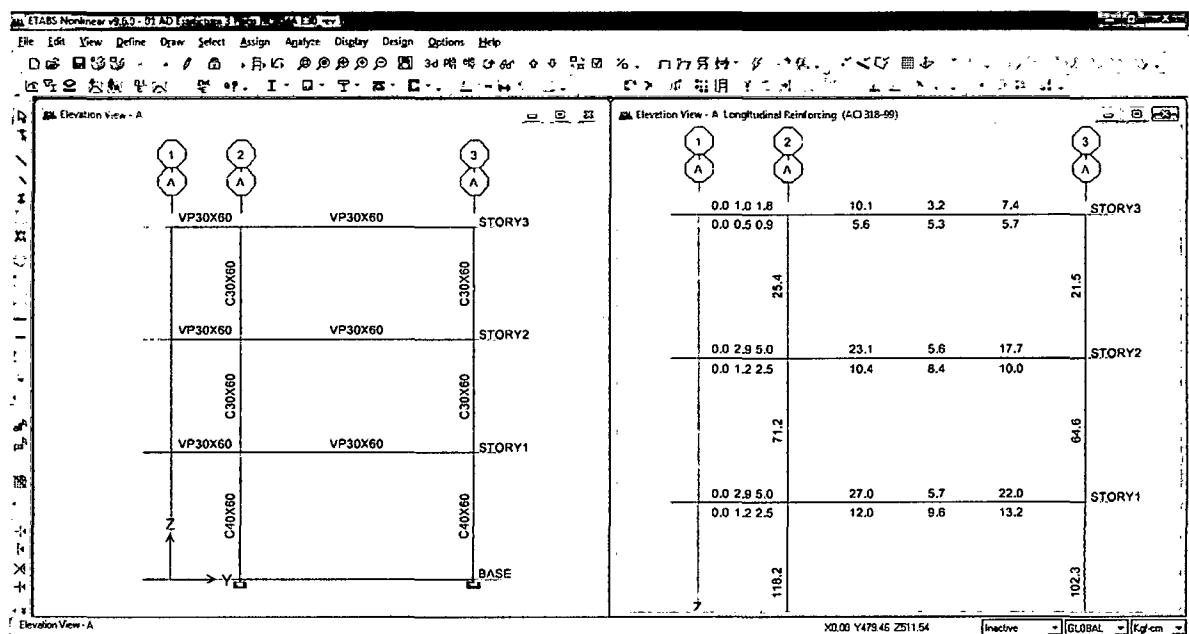

18. Definir la combinación de diseño para el cálculo de acero según norma E030.

Esta combinación será la envolvente para cada caso de análisis.

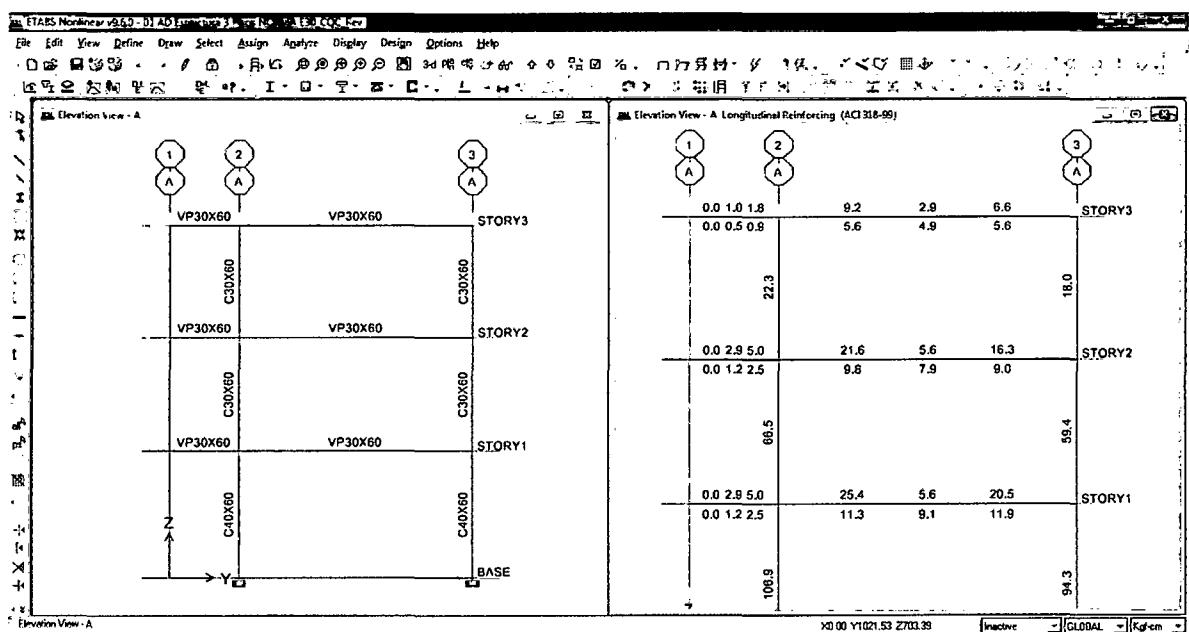

Ejecutar el programa para diseño de acero seleccionando (ACI 318-99) esta nos brinda los factores de reducción de resistencia utilizados por la Norma E060.

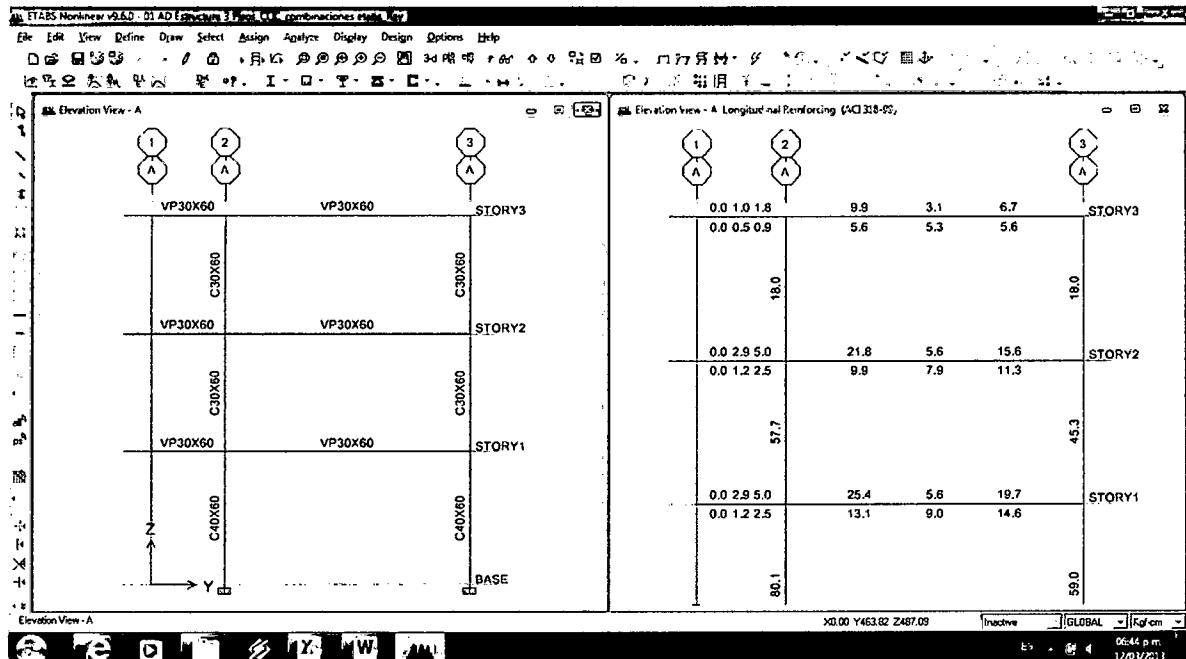

19. Resultado de acero longitudinal eje A-A Norma E030 espectro (0.75SRSS+0.25ABS)

20. Resultado de acero longitudinal eje A-A Norma E030 espectro (CQC)

## 21. Resultado de acero longitudinal eje A-A Norma ACI 318-99 espectro (CQC configuración ETABS)

### 2.6.1 Verificación de las 3 simulaciones.

#### a. Verificación del cortante estático.

## **CONCLUSIONES Y RECOMENDACIONES**

### **4.1. CONCLUSIONES:**

Se logró evaluar el programa ETABS mediante las tres simulaciones de los modelos de la estructura de tres niveles, con cargas y condiciones de configuración iguales, obteniéndose los siguientes resultados:

4.1.1 El análisis de la simulación del modelo estructural entre la Norma E030 espectro (0.75SRSS+0.25ABS) vs Norma E030 espectro (CQC), se logró una reducción de acero en vigas de hasta 10%, en columnas una reducción de hasta el 16% con la Norma E030 espectro (CQC)

4.1.2 El análisis de la simulación del modelo estructural entre la Norma E030 espectro (0.75SRSS+0.25ABS) vs Norma ACI-318-99 espectro (CQC predeterminado ETABS), se logró un incremento en vigas del orden de hasta 10.00%, en columnas una reducción de hasta 39% con la Norma ACI-318-99 espectro (CQC predeterminado ETABS).

4.1.3 El análisis de la simulación del modelo estructural entre la Norma E030 espectro (CQC) vs Norma ACI-318-99 espectro (CQC predeterminado ETABS), se logró determinar un incremento en vigas del orden de hasta el 29%, en columnas una reducción de hasta 37% con la Norma ACI-318-99 espectro (CQC predeterminado ETABS).

4.1.4 Se determinó que la mejor configuración del programa ETABS para el diseño de estructuras de concreto armado es aplicando la Norma E030 con espectro CQC ya nos dimensiona menor acero.

4.1.5 El algoritmo que nos brinda menor dimensionamiento de acero y cumple con la Norma E030 es el realizado en el procedimiento 2.1.3 (Página 56)

4.1.6 El análisis ACI 318-99 espectro CQC nos incrementa en vigas 10% y nos reduce en columnas 37%, también podría usarse para el diseño de una estructura bajo la responsabilidad del ingeniero diseñador.

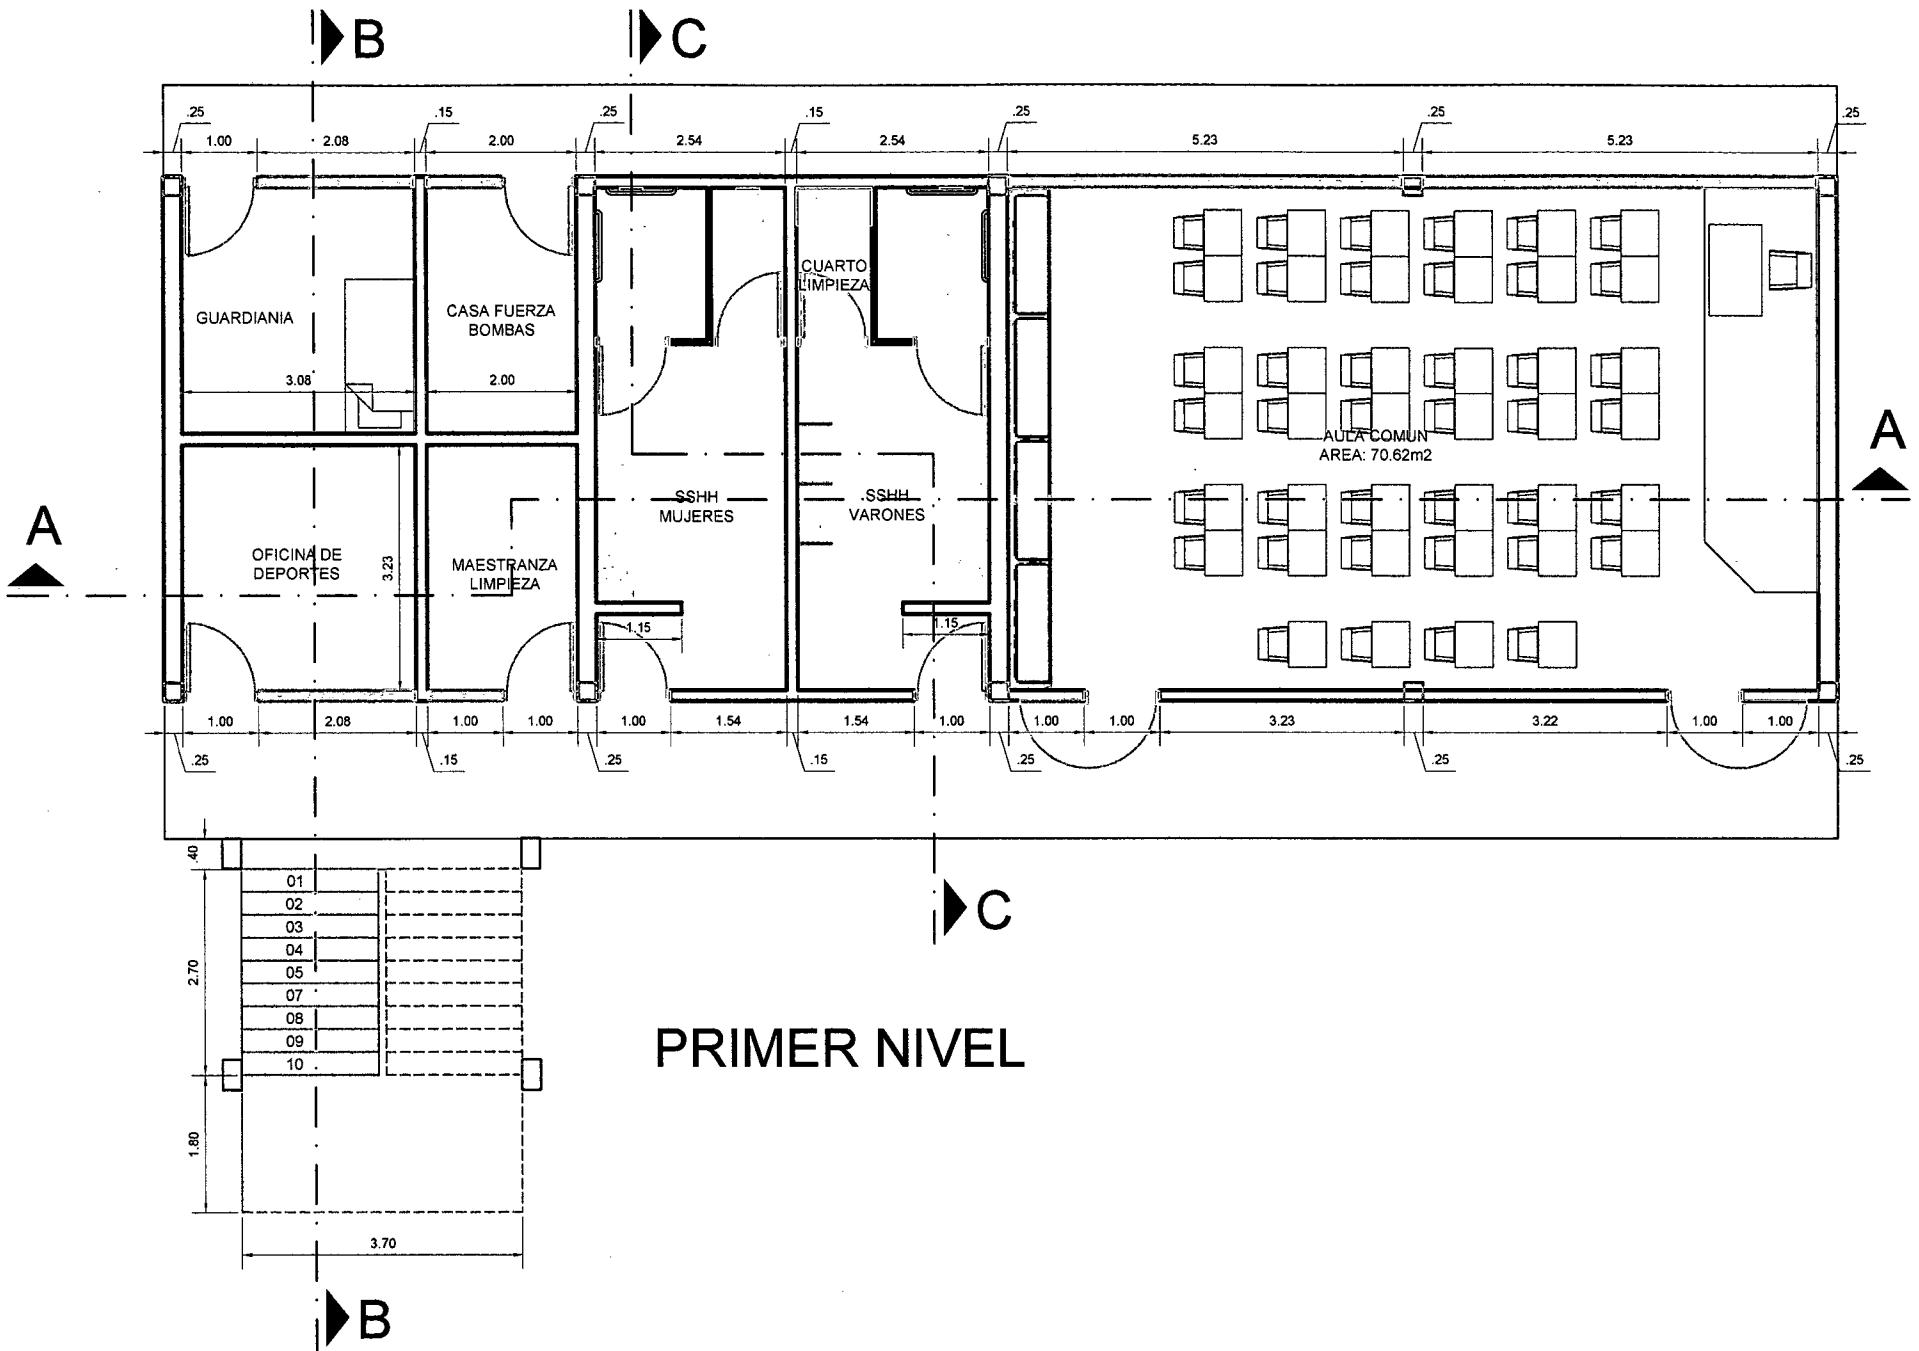

## **4.2. RECOMENDACIONES:**

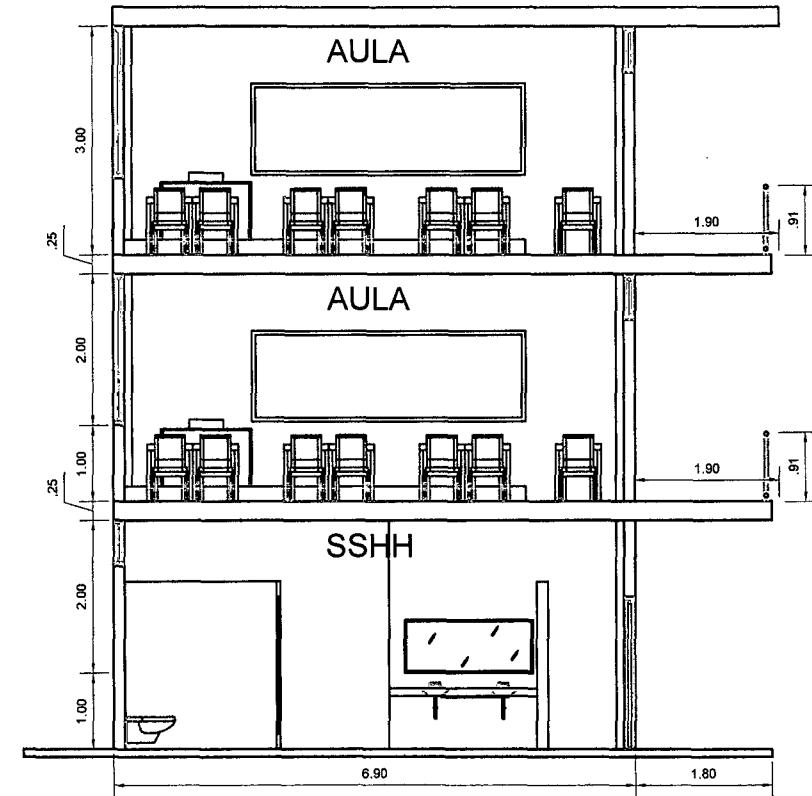

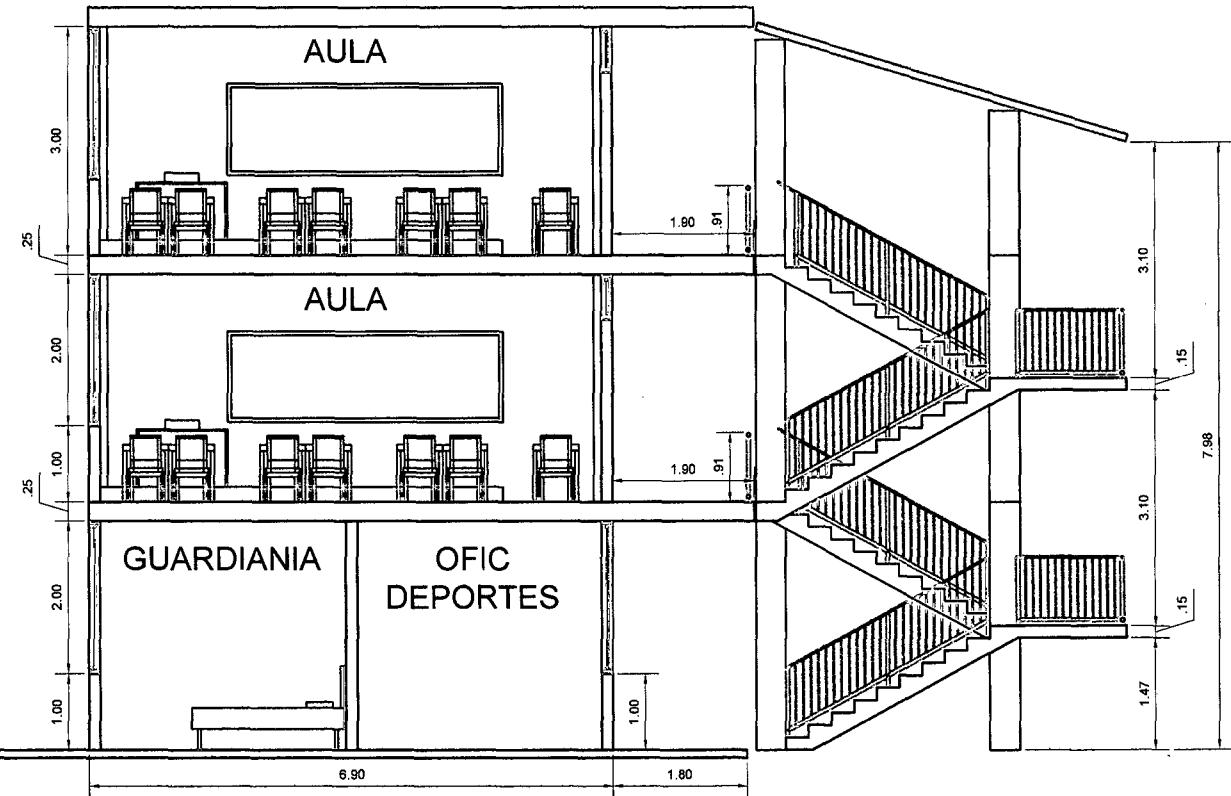

- 4.2.1. Se recomienda tener bien definidas las cargas y parámetros de la edificación a analizar con el programa ETABS ya que éstas pueden variar considerablemente el cálculo de acero de los elementos estructurales.
- 4.2.2. De las tres simulaciones realizadas se recomienda analizar una estructura de concreto armado aplicando la Norma E030 con espectro de diseño CQC, ya que nos dimensiona menos acero tanto en vigas como en columnas en comparación con la Norma E030 espectro de diseño ( $0.75\text{SRSS}+0.25\text{ABS}$ ) y Norma ACI 318-99 espectro (CQC).
- 4.2.3. Recomendamos como tema de investigación realizar el análisis **Push-Over** para cada una de las tres simulaciones consideradas en el presente tema de investigación, y analizar en qué caso se da el mejor comportamiento estructural y ver cómo se va generando las rótulas plásticas en cada simulación.
